Diffusion couples of aluminum nitride (AlN) and Ti were annealed under an argon atmosphere at temperatures ranging from 1300°C to 1500°C for 0.5–36 h. The morphologies, crystal structures, and chemical compositions of the reaction zones at AlN/Ti interfaces were characterized using analytical scanning electron microscopy and analytical transmission electron microscopy. An interfacial reaction zone, consisting of TiN, $\tau_2$-Ti$_2$AlN, $\gamma$-Ti$_3$AlN, $\varepsilon$-Ti$_3$Al, and a two-phase ($\gamma_2$-Ti$_3$Al + $\varepsilon$-Ti) region in sequence, was observed in between AlN and Ti after annealing at 1300°C. The $\gamma_2$-Ti$_3$Al region revealed equiaxed and elongated morphologies with [0001]equiaxed // [110] elongated and (1010)equiaxed // (1122)elongated. In the two-phase ($\gamma_2$-Ti$_3$Al + $\varepsilon$-Ti) region, $\gamma_2$-Ti$_3$Al and $\varepsilon$-Ti were found to satisfy the following orientation relationship: [0001]$_{\gamma_2}$ // [0001]$_{\text{Ti}_3\text{Al}}$ and (1100)$_{\gamma_2}$ // (1100)$_{\text{Ti}_3\text{Al}}$. The $\gamma$-TiAl and a lamellar two-phase ($\gamma$-TiAl + $\varepsilon$-Ti$_2$Al) structure, instead of $\tau_2$-Ti$_2$AlN, were found in between $\gamma_2$-Ti$_3$AlN and $\gamma$-Ti Al annealing at 1400°C. The orientation relationship of $\gamma$-TiAl and $\varepsilon$-Ti$_2$Al in the lamellar structure was identified to be as follows: [011]$_{\gamma}$ // [011]$_{\gamma_2}$ and (111)$_{\gamma}$ // (110)$_{\gamma_2}$. Compared with the reaction zone after annealing at 1400°C, the $\gamma$-TiAl was not found at the interface after annealing at 1500°C. The microstructural development resulting from isothermal diffusion at 1300°C and subsequent cooling at the interface are explained with the aid of the Ti–Al–N ternary phase diagram and a modified Ti–Al binary phase diagram.

1. Introduction

Aluminum nitride has been considered one of the most promising substrate materials for use in semiconductor, microwave, optical, electronic, and high-performance applications, because of its high thermal conductivity ($\approx 320$ W·m$^{-1}$·K$^{-1}$), low dielectric constant ($\approx 8.8$), a high electric resistivity ($\approx 10^{12} − 10^{14}$ Ω·cm), and coefficient of thermal expansion similar to that of silicon.1,2 Meanwhile, Ti is a highly active metal and easily reacts with almost all ceramics,3-9 and a high adhesion or bond strength can be achieved by the interface reactions between titanium and the substrate materials. In some applications for microelectronics such as ceramic packaging and metallization,10-14 where aluminum nitride is placed in direct contact with titanium, the interfacial properties of AlN and Ti are crucial in determining the quality and reliability of the electrical package and its high-temperature applications.

Previous investigations on the interfacial reaction of AlN and Ti have been very limited, most of them concerning the reaction of AlN with Ti thin films15-19 or Ti-containing brazing foils.20-22 While available data on the microstructure of the AlN–Ti interfacial reaction zone are often controversial, it is imperative to explore the interdiffusion reactions and mechanisms in the AlN/Ti bonding process in order to make more effective use of AlN and Ti as well.

Some previous studies regarding the thin-film metallization of AlN have been published.15-19 As far as the interface reaction between the Ti thin film and the AlN substrate was concerned, Westwood and Notis15,16 found the formation of TiN and TiAl$_3$ at the interface after annealing at 600°C for 30 min in an oxygen-free sample. He et al.23 investigated the interface reactions of Ti thin films with AlN substrate in the temperature range of 600°C–800°C using X-ray diffractometry (XRD) and Rutherford backscattering spectroscopy (RBS). They indicated that the TiAl$_3$ phase was formed at the interface adjacent to the AlN substrate, while TiN, Ti$_2$N$_{1−x}$, and Ti$_3$N$_x$ were formed above the TiAl$_3$ layer. Yasumoto et al.18 deposited a Ti thin film on AlN with radio frequency (rf) sputtering, revealing that under an argon atmosphere, TiAl$_3$ was formed at 700°C for 60 min, and TiAl$_3$, Ti$_2$N, and TiN were detected after annealing at 830°C for 60 min by using XRD. In the study of the interdiffusion and reaction of Ti (thin film) and AlN (substrate) using RBS and transmission electron microscopy (TEM), Imanaka and Notis19 found Ti$_2$AlN at the interface after annealing at 800°C–950°C. Recently, Pinkas et al.24 worked on the early stages of interface reactions between Al and Ti thin films after annealing at 600°C for 1–10 h. They claimed that the AlN decomposed at the AlN/Ti interface and its products, Al and N, reacted with Ti to produce an AlN/Ti$_x$Al$_{(1-x)}$N$_y$/Ti$_{(2-x)}$Al$_x$ phase sequence.

As for the brazing of AlN,20-22 Carim and Loehman20 reported that continuous TiN and (Ti, Cu, Al)$_3$N at the interface of AlN and Ag–Cu–Ti foil were formed after annealing at 900°C for 5–30 min. By using TEM and electron probe microanalysis, Loehman13 and Loehman and Tomiska25 indicated that TiN$_{0.7}$ was detected at the interface of AlN and Ag–26.7Cu–4.5Ti after reaction at 900°C for 30 min in an argon atmosphere.

Among other previous studies on the interfacial reaction of AlN and Ti, El-Sayed et al.26 characterized the reaction zone microstructure of AlN/Ti (20 or 50 μm thick)/AlN joints after annealing at 1050°C–1200°C for 2–20 h in vacuum. The reflection peaks of TiN, Ti$_2$AlN, Ti$_3$AlN, and Ti$_3$Al were observed in the X-ray diffraction spectra taken from the fracture surfaces of annealed joints. Up to 1200°C for 20 h, both TiN$_{1−x}$ and Ti$_2$AlN did not grow significantly, but the growth kinetics of Ti$_3$Al followed the parabolic law. Paransky et al.26-28 investigated the interfacial reactions between AlN particles and the Ti matrix, as well as AlN–Ti diffusion couples, after annealing in the temperature range from 900°C to 1100°C using energy-dispersive spectroscopy (EDS) and electron back-scattered diffraction attached to a scanning electron microscope (SEM). A phase sequence of TiN, Ti$_3$Al$_{0.3}$N$_{0.7}$, and Ti$_3$Al was observed at the interface of Ti and AlN. While the binary nitride TiN and the ternary nitride Ti$_3$AlN exhibited a complex interpenetrating morphology, a lamellar two-phase region was also observed in between the two phases.
observed between Ti$_3$AlN and Ti$_3$Al layers after annealing at 1000° and 1100°C.

Many applications of the industrial AlN/Ti joints, such as metallization, brazing, and the composites mentioned above, are determined by the characteristics of the interface between AlN and Ti. In the last few decades, extensive studies have been carried out on the interface reaction between aluminum nitride and titanium. However, the microstructure evolution at the interface has not been elucidated to date, even though a fundamental understanding of reaction and diffusion mechanisms is of great importance for industrial applications and scientific meaning.

The present study is devoted to the microstructural characterization of the interfacial reaction zone in AlN and Ti diffusion couples after annealing at temperatures ranging from 1300° to 1500°C by SEM/EDS and TEM/EDS. We will try to explain the microstructural development at the Ti/AlN interface on the basis of the ternary Al–Ti–N phase diagram and the diffusion paths that connect the phases formed by the reaction between AlN and Ti. The present study is expected to contribute to the understanding of the ternary Ti–Al–N system at high temperatures and to aid in the processing of ceramic-metal joints.

![Fig. 1. Scanning electron micrographs of the interface between AlN and Ti after annealing at: (a) 1300°C/36 h; (b) 1400°C/36 h; and (c) 1500°C/36 h.](image)
II. Experimental Procedure

Highly pure AlN plates (SH-15, Tokuyama Soda Corp., Tokyo, Japan) and Cp-Ti plates (99.7% purity, Alfa Aesar, Ward Hill, MA) were used in this study. All the plates (about 15 mm × 10 mm × 4 mm in dimension) were ground with a diamond (15 μm) matted disk and then polished with a diamond paste (3 μm) and an alumina suspension (1 μm) using a precision polishing machine (Model Minimet 1000, Buehler Ltd., Lake Bluff, IL). The specimens were then rinsed in acetone (ultrasonic bath) and distilled water, and then air-dried.

In order to characterize the microstructure of the Ti/AlN interface, samples were prepared as a sandwich mode with the Ti metal placed in between two pieces of AlN. Then, the samples were annealed in an argon atmosphere (with O<sub>2</sub>< 1 ppm, H<sub>2</sub>O< 76 ppm, THC< 0.5 ppm, and N<sub>2</sub> < 3 ppm) under a pressure of 2 MPa at temperatures ranging from 1300 to 1500 °C, with a holding time from 0.5 to 36 h, and then the specimen was continuously cooled down to room temperature at a rate of 10 °C/min.

The cross-sectional TEM and SEM samples were prepared as follows: each annealed sample was cut into two halves in a direction perpendicular to the interface of AlN/Ti, and then ground and polished by the standard procedures as mentioned above. The samples were etched with the Kroll reagent (10 mL HF + 30 mL HNO<sub>3</sub> + 60 mL H<sub>2</sub>O) in order to emphasize the features of different phases and to remove the deformed surface layer. Thereafter, the samples were rinsed in acetone (ultrasonic bath) and distilled water, and then air-dried. To avoid charging, all the SEM samples were coated with a thin layer of platinum (finished preparation of SEM samples). The cross-sectional slab was ground down to an 80–100 μm thickness using a precision polishing machine; then, the sample was thinned to 20–30 μm by dimpling, and finally argon ion milled at 5 kV and 20 μA (finished preparation of TEM samples).

Microstructural characterization of the cross-sections of AlN/Ti was carried out using a high-resolution scanning electron microscope (Model JSM-6500, JEOL, Tokyo, Japan) and an analytical TEM (Model 2000Fx, JEOL). The Cliff–Lorimer standardless technique was used to analyze the compositions of the various phases. The technique was performed on the TEM, equipped with an ultra-thin window EDS detector (Model 9900, EDAX International, Prairie View, IL). A conventional ZAF correction procedure included in the LINK ISIS software was used for the quantitative analyses.

**Fig. 2.** (a) Bright-field image of the AlN/Ti interface after annealing at 1300 °C for 3 h; (b) selected area diffraction pattern (SADP) of TiN, Z = [001]; (c) SADP of τ<sub>2</sub>-Ti<sub>3</sub>N<sub>1</sub>, Z = [1120]; and (d) SADP of τ<sub>1</sub>-Ti<sub>3</sub>N<sub>1</sub>, Z = [001].
III. Results and Discussion

The products formed in the AlN/Ti interfacial reaction zone are listed in Table I, after annealing at 1300 –1500°C for various periods. The reaction zone consisted of TiN, \( \tau_2 \)-Ti2AlN, \( \tau_1 \)-Ti3AlN, \( \alpha_2 \)-Ti3Al, and a two-phase (\( \alpha_2 \)-Ti3Al+\( \alpha \)-Ti) region in sequence after annealing at 1300°C. The \( \gamma \)-TiAl and a lamellar two-phase (\( \gamma \)-TiAl+\( \alpha_2 \)-Ti3Al) structure were found instead of \( \tau_1 \)-Ti3AlN in between \( \tau_2 \)-Ti2AlN and \( \alpha_2 \)-Ti3Al after annealing at 1400°C. In comparison with the results after annealing at 1400°C, \( \gamma \)-TiAl was not formed at the interface after annealing at 1500°C. It was noted that there were some exceptions for the initial transition stage. For instance, no \( \tau_2 \)-Ti2AlN had been found after annealing at 1350°C for 0.5 h, while \( \gamma \)-TiAl and the lamellar two-phase (\( \gamma \)-TiAl+\( \alpha_2 \)-Ti3Al) layer did not exist after annealing at 1400°C for 0.5 h, whereas a layer of \( \gamma \)-TiAl was found after annealing at 1500°C for 0.5 h. In contrast to the reaction of AlN and \( \alpha \)-Ti thin films annealed at lower temperatures (e.g., 600°–800°C),23,24 no TiAl3 was found in the present study.

(1) SEM/EDS Analyses

Figure 1 shows the secondary electron images of the cross-sectional microstructures of the AlN/Ti diffusion couples after annealing at various temperatures for 36 h. Figure 1(a) displays that the reaction zone between AlN and Ti consists of TiN, \( \tau_2 \)-Ti2AlN, \( \tau_1 \)-Ti3AlN, \( \alpha_2 \)-Ti3Al, and a two-phase (\( \gamma \)-TiAl+\( \alpha \)-Ti) region in sequence after annealing at 1300°C for 36 h. The \( \gamma \)-TiAl layer and lamellar structure (\( \gamma \)-TiAl+\( \alpha_2 \)-Ti3Al), instead of Ti3AlN, were formed between the Ti2AlN and Ti3Al. Figure 1(c) displays the reaction phase sequence of TiN/\( \tau_2 \)-Ti2AlN/\( \gamma \)-TiAl/\( \alpha_2 \)-Ti3Al/Ti3Al/\( \alpha \)-Ti. The TiAl layer was not found at the interface after annealing at 1500°C for 36 h as mentioned above.

El-Sayed et al.25 found that the sequence of the reaction layer was AlN/TiN/\( \tau_1 \)-Ti3AlN/\( \alpha_2 \)-Ti3Al/\( \alpha \)-Ti. However, they did not observe the lamellar two-phase (\( \gamma \)-TiAl+\( \alpha_2 \)-Ti3Al) and (\( \gamma \)-TiAl+\( \alpha \)-Ti) layers. Paransky et al.26-28 showed that the sequence of TiN, \( \tau_1 \)-Ti3AlN, and \( \alpha_2 \)-Ti3Al was formed at the interface of Ti (matrix) and AlN (particle) and that the TiN and \( \tau_1 \)-Ti3AlN exhibited a complex interpenetrating morphology. Furthermore, a lamellar two-phase region was also observed between \( \tau_1 \)-Ti3AlN and \( \alpha_2 \)-Ti3Al layers after annealing at 1000° and 1100°C. However, in the present study, \( \tau_2 \)-Ti2AlN and a
two-phase ($\alpha_2$-Ti$_3$Al+$\gamma$-Ti) region existed at the interface after annealing at 1300°C, while $\gamma$-TiAl and a lamellar structure ($\gamma$-TiAl+$\alpha_2$-Ti$_3$Al) were found in the interface at 1400°C. In the temperature range used in this study, two lamellar layers were found: one layer ($\alpha_2$-Ti$_3$Al) was developed because of the precipitation of $\alpha_2$-Ti$_3$Al from $\alpha$-Ti; the other layer ($\alpha_2$-Ti$_3$Al+$\gamma$-TiAl) was formed because of the eutectoid reaction ($\alpha$-Ti $\rightarrow$ $\alpha_2$-Ti$_3$Al+$\gamma$-TiAl) during cooling.

In Fig. 1, the nitride layers, e.g., TiN, $\tau_2$-Ti$_2$AlN, and $\tau_1$-Ti$_3$AlN, were so brittle that there were cracks in these layers. The crack formation was attributed to the mismatch of thermal expansion coefficients between aluminum nitride and titanium, resulting in a significant residual thermal stress.

It was also noted that there existed some pores in aluminate layers (i.e., $\gamma$-TiAl, $\alpha_2$-Ti$_3$Al, etc.) of the reaction zone. These pores were caused because of the formation of nitrogen bubbles during cooling. A significant amount of nitrogen was dissolved in aluminate layers on heating. However, the solubility of nitrogen in aluminate layers sharply decreased with decreasing temperature, so that nitrogen was supersaturated. The nitrogen bubbles were thus precipitated through a nucleation and growth mechanism like the gas bubble formation commonly encountered in the casting of alloys. It is worth noting that the decrease in the solubility of nitrogen, not the solubility itself, gave rise to the precipitation of nitrogen bubbles or pores during cooling. This is the reason why nitrogen bubbles primarily existed in $\alpha_2$-Ti$_3$Al, although the solubility of nitrogen in $\alpha_2$-Ti$_3$Al is much larger than that in $\gamma$-TiAl. Like the existence of spherical oxygen bubbles in Ti because of the Ti/ZrO$_2$ interfacial reaction, nitrogen bubbles were formed in $\gamma$-TiAl even though the $\alpha$-Ti is capable of dissolving a large amount of oxygen. On comparing Figs. 1(a)-(c), it was concluded that the amount of bubbles increased with annealing temperature.

(2) TEM/EDS Analyses

Figure 2(a) shows the bright-field (BF) image of the AlN/Ti interface after annealing at 1300°C for 3 h, showing the phases of TiN, $\tau_2$-Ti$_2$AlN, and $\tau_1$-Ti$_3$AlN. Note that the two-phase ($\alpha_2$-Ti$_3$Al+$\gamma$-TiAl) region has not been shown in Fig. 2(a). As shown in Fig. 2(b), the selection area diffraction pattern (SADP) of TiN was indexed as a cubic unit cell with lattice parameters of $a = 0.426 \text{ nm}$. The TEM/EDS analyses revealed that the layers of $\tau_2$-Ti$_2$AlN and $\tau_1$-Ti$_3$AlN were ternary compounds with the approximate compositions Ti:Al:N = 2:1:1 and Ti:Al:N = 3:1:1, respectively. The first extensive study of phase equilibria in the Ti-Al-N system was conducted by Schuster and Bauer, with two isothermal sections at 1000°C and 1300°C being
Recently, Pietzka and Schuster showed that three ternary nitride phases Ti₃Al₂N₂, Ti₂AlN₁, and Ti₃AlN₁ are present in a much more detailed section at 1300°C. The SADPs of t₂-Ti₂AlN and t₁-Ti₃AlN are shown in Figs. 2(c) and (d), respectively. On indexing these SADPs, it was found that t₂-Ti₂AlN had a hexagonal crystal structure with the lattice parameters \(a = 0.299 \text{ nm}\) and \(c = 1.361 \text{ nm}\), while the t₁-Ti₃AlN was indexed to be a cubic unit cell with the lattice parameter \(a = 0.4284 \text{ nm}\).

The t₂-Ti₃Al layer, as shown in Figs. 1(a) and 2(a), displayed two distinct features, whose BF images are displayed in Figs. 3(a) and (b), respectively. The t₂-Ti₃Al layer had two different morphologies, i.e., equiaxed t₂-Ti₃Al and elongated t₂-Ti₃Al. Both equiaxed t₂-Ti₃Al and elongated t₂-Ti₃Al had the same crystal structure but with different compositions (the Al concentrations ranging from 22 to 39 at.%). The equiaxed structure marked “A” in Fig. 3(a) was corresponding to the regions also marked as “A” in Figs. 1(a) and 2(a), respectively. In the same way, the elongated texture structure marked “B” in Fig. 3(b) was corresponding to the regions both marked as “B” in Figs. 1(a) and 2(a). The EDS quantitative analyses indicated that the equiaxed t₂-Ti₃Al in Fig. 3(a) and elongated t₂-Ti₃Al in Fig. 3(b) were 66.90 at.% Ti, 25.07 at.% Al, 8.03 at.% N, and 62.21 at.% Ti, 23.42 at.% Al, and 14.37 at.% N, respectively.

The elongated t₂-Ti₃Al grains in Fig. 3(b) were well aligned nearly perpendicular to the interface of AlN/Ti. As Al and N diffuse much faster than Ti, the Ti region will be subjected to a state of compression because of the interdiffusion. However, the fact that the equiaxed t₂-Ti₃Al became elongated along the direction perpendicular to the interface is attributed to the mismatch in the thermal expansion coefficient between AlN and Ti.

Based upon our TEM investigation, the equiaxed t₂-Ti₃Al was not randomly oriented, because it displayed the same contrast when the specimen was tilted. The equiaxed t₂-Ti₃Al in Fig. 3(a) was likely to be formed by recrystallization. Previous studies have reported that the t₂-Ti₃Al alloys could exhibit admirable superplasticity of elongation greater than 1200% at temperatures between 960°C and 1000°C and strain rates between \(10^{-4}\) and \(10^{-5} \text{s}^{-1}\). It is believed that the large deformation of textured t₂-Ti₃Al is likely to trigger the recrystallization. Figure 3(c) displays the variation in the grain sizes of t₂-Ti₃Al along the direction from the AlN side (bottom) to the Ti side (top). The grain size varies from 150 to 450 nm, implying the different degrees of grain growth after recrystallization. When the t₂-Ti₃Al, with a deformation texture, was recrystallized, the new equiaxed grains usually had a preferred orientation. However, the orientation of the equiaxed t₂-Ti₃Al was different from that of the textured t₂-Ti₃Al. The SADP, as shown...
in Fig. 3(d), revealed that the orientation relationship of the equiaxed and the elongated α_2-Ti_3Al should be as follows: [0001]_{equiaxed} // [1100]_{elongated} and (1010)_{equiaxed} // (1122)_{elongated}. The fact that the equiaxed α_2-Ti_3Al had a recrystallization texture was because of the influence that the texture of the α_2-Ti_3Al had on the nucleation and/or growth of the new grains.

Figures 4(a) and (b) show the bright and dark field images of the two-phase (α_2-Ti_3Al+α-Ti) layer near the Ti side, respectively. In Fig. 4(b), it can be seen that α-Ti is distributed along the grain boundaries of α_2-Ti_3Al. The lattice parameters of α-Ti, calculated from the SADPs in Fig. 4(c), were a = 0.310 nm and c = 0.441 nm, while those of α_2-Ti_3Al were a = 0.605 nm and c = 0.487 nm. The a value of α_2-Ti_3Al was approximately twice that of α-Ti. It was inferred that the α_2-Ti_3Al was precipitated in the matrix of α-Ti. From the SADPs, where the superlattice diffraction spots of α_2-Ti_3Al were clearly observed, the α_2-Ti_3Al precipitates were found to satisfy the following orientation relationship with respect to α-Ti: [0001]_{α_2-Ti_3Al} // [0001]_{α-Ti} and (1100)_{α_2-Ti_3Al} // (1100)_{α-Ti}. The orientation relations are schematically demonstrated in Fig. 4(d).

According to the Ti–Al binary phase diagram, α_2-Ti_3Al was stable up to 1210°C, being a nonstoichiometric compound with a relatively wide range extending from 23 to 35 at.%. It seemed that α_2-Ti_3Al could only be formed during isothermal annealing below 1210°C. However, the α_2-Ti_3Al phase was formed after isothermal annealing at temperatures higher than 1300°C, as mentioned previously. This implied that the α_2-Ti_3Al precipitated from α-Ti during cooling. The existence of (α-Ti+α_2-Ti_3Al), α_2-Ti_3Al, or (α_2-Ti_3Al+γ-TiAl) various aluminide layers in the reaction zone of the AlN–Ti diffusion couple, which was isothermally annealed above 1300°C, can be explained by a modified Ti–Al binary phase diagram, and will be described afterwards.

Figure 5(a) shows the BF image of the AlN/Ti interfacial reaction zone after annealing at 1500°C for 0.5 h, showing α_2-Ti_2AlN, γ-TiAl, and the two-phase (γ-TiAl+α_2-Ti_3Al) layer. The inset on the upper right corner shows the SADP of γ-TiAl with the zone axis of [110]. The (γ-TiAl+α_2-Ti_3Al) lamellar structure is displayed at a higher magnification in Fig. 5(b). The two-phase (γ-TiAl+α_2-Ti_3Al) region usually forms a lamellar morphology consisting of colonies of thin parallel α_2-Ti_3Al and γ-TiAl platelets. Based upon the Ti–Al phase diagram, the lamellar structure resulted from the eutectoid reaction of α→α_2+γ. From the SADPs of the lamellar structure (Fig. 5(c)) and its corresponding schematic diagram (Fig. 5(d)), the...
orientation relationship of γ-TiAl and 2γ-Ti2Al was identified: [011]_{TiAl}∥[2110]_{γTiAl} and [111]_{TiAl}∥[0110]_{γTiAl}. In addition, the schematic SADP patterns in Fig. 5(d) show some extra spots caused by the structure of twinning in tetragonal crystals of γ-TiAl. The matrix of γ-TiAl was oriented with its [011] zone axis parallel to the electron beam, while the twinning plane (111), was in the edge-on direction along the electron beam. The diffraction patterns of the matrix and the twin were related by a mirror reflection across the (111) twinning plane or by a rotation of 180° around the normal to the twinning plane.

(3) Microstructural Development and Diffusion Path at 1300°C

When Ti comes into contact with AlN, the system becomes unstable. It is generally acknowledged that the interfacial reactions between Ti and AlN include the following steps. AlN is reduced under the effect of Ti at the annealing temperature. The decomposed Al and N atoms then diffuse into the Ti, and they react with each other to produce binary or ternary nitrides and aluminides. While the nitrides are stable during the subsequent cooling, the aluminides will be subjected to phase transformation based on the Ti-Al binary phase diagram.

Figure 6 illustrates the relationship between the Ti–Al–N phase diagram and the microstructure developed in the Ti/AlN diffusion couple, similar to the case for the interface between carbon and Ti (Al,N) stabilizers, the Ti stabilizers, the Al stabilizers, the TiN, TiAlN, Ti3Al, Ti2AlN, AlN, AlN, and AlN). As shown in Fig. 6(b), the layers of TiN, Ti2AlN, Ti3AlN, and AlN(N) were subjected to phase transformation during the subsequent cooling, causing the formation of the Ti–Al binary phase diagram.

The phase transformation of aluminides, mentioned above, can be shown schematically in the Ti–Al binary phase diagram as shown in Fig. 7. Because nitrogen is an α-Ti stabilizer, the β/ (α+β) and (α+β)/α boundaries of the Ti–Al binary phase diagram are shifted upward by dissolving N atoms. The β-Ti layer abutting the reaction-unaffected Ti, with a small amount of Al and N in solid solution, was transformed into α-Ti on cooling, as indicated by line 1 in Fig. 7. The α-Ti+β-Ti layer at 1300°C was transformed into the α-Ti+2γ-Ti2Al layer after cooling (line

![Figure 7](Image 82x450 to 482x744)

**Fig. 7.** A modified Ti–Al phase diagram because of the stabilization of α-Ti by dissolving N (see the dashed line),35 showing the cooling processes of the various aluminides after annealing at 1300°C (lines 1–3) and at 1400°C (lines 4 and 5). The increase in the α→β transformation temperature has been exaggerated for clarification.
As it was on cooling (line 5 in Fig. 7). It is worth noting that no indicated by line 4 in Fig. 7, while the fusion after annealing at 1400°C, the diffusion species N atoms will go into Ti, leading to the formation of TiN with Al in solid solution. The formation of TiN in the initial stage can be expressed by the following reactions, as shown in Fig. 8(a):39

\[
\text{AlN} \rightarrow \text{Al} + \text{N} \quad \Delta G^0 = -159,770 \text{ (J/mole)}
\]

(1)

\[
\text{Ti} + \text{N} \rightarrow \text{TiN} \quad \Delta G^0 = -188,108 \text{ (J/mole)}
\]

(2)

\[
\text{AlN} + \text{Ti} \rightarrow \text{TiN} + \text{Al} \quad \Delta G^0 = -347,878 \text{ (J/mole)}
\]

(3)

The diffusion of N atoms and Al atoms in TiN is much faster than that of Ti atoms in AlN (diffusivities of N and Al in TiN are \(5.4 \times 10^{-3} \text{ cm}^2/\text{s}\) at 1000–1500°C and \(3 \times 10^{-14} \text{ cm}^2/\text{s}\) at 300–550°C; the diffusivity of Ti in AlN is \(4 \times 10^{-17} \text{ cm}^2/\text{s}\) at 1280–1400°C).40 Thus, Al and N continuously diffuse through the TiN layer and reaction (2) takes place at the interface of TiN and Ti. The highly negative Gibbs free energy change of the reaction (3) indicates that the reaction between aluminum nitride and titanium is thermodynamically favorable.

(B) Second Stage: Formation of Ti3AlN and Various Titanium Aluminides: When the concentrations of Al and N increase to a certain amount, \(\tau_1\)-Ti3AlN is formed, as shown in Fig. 8(b), at the interface of TiN/Ti according to the following reaction:

\[
3\text{Ti} + \text{Al} + \text{N} \rightarrow \tau_1\text{-Ti}_3\text{AlN}
\]

(4)

The formation of \(\tau_1\)-Ti3AlN instead of \(\alpha\)-Ti2AlN at this stage is consistent with the fact that \(\tau_1\)-Ti3AlN was found after annealing at 1300°C/0.5 h, which was at a relatively early stage. Meanwhile, excess Al and N atoms further go into Ti as a solid solution, leading to the formation of various titanium aluminonitrides, for example, \(\alpha\)-Ti(Al,N) and the \(\alpha\)-Ti(Al,N)+\(\beta\)-Ti(Al,N) two-phase region.

(C) Third Stage: Formation of Ti2AlN: As shown in Fig. 8(c), \(\tau_2\)-Ti2AlN is formed at this stage. The growth of the \(\tau_2\)-Ti2AlN was controlled by the diffusion of Al and N through TiN, accumulating at the TiN/\(\tau_1\)-Ti3AlN interface, leading to the disappearance of \(\tau_1\)-Ti3AlN based upon the following reaction:

\[
\tau_1\text{-Ti}_3\text{AlN} + \frac{1}{2}\text{Al} + \frac{1}{4}\text{N} \rightarrow \frac{3}{2}\tau_2\text{-Ti}_2\text{AlN}
\]

(5)

(D) Fourth Stage: Formation of \(\alpha\)-Ti2Al and/or the Two-Phase Layer (\(\alpha\)-Ti2Al/\(\alpha\)-Ti) During Cooling: Figure 8(d) shows that the \(\alpha\)-Ti(Al,N)+\(\beta\)-Ti(Al,N) two-phase region was transformed into the \(\alpha\)-Ti2Al/\(\alpha\)-Ti two-phase layer, while the \(\alpha\)-Ti(Al,N) layer was transformed into the \(\alpha\)-Ti2Al layer during cooling, depending upon the local composition. Not shown in Fig. 8(d) is that the \(\beta\)-Ti(Al,N) was transformed into the \(\alpha\)-Ti(Al,N). The phase transformations mentioned above can be expressed by the following reactions,

\[
\beta\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti(Al,N)}
\]

(6)

\[
\alpha\text{-Ti(Al,N)} + \beta\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti(Al,N)} + \alpha\text{-Ti}_2\text{Al(N)}
\]

(7)

\[
\alpha\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti}_2\text{Al(N)}
\]

(4) Reaction Zone Growth Mechanisms at 1300°C

Based upon the results and the discussion mentioned above, an attempt was made to propose an interfacial reaction model between AlN and Ti. The formation mechanisms for several different stages at 1300°C, as an example, are schematically shown in Fig. 8.

(A) First Stage: Formation of TiN: In the first stage, AlN decomposes at the original AlN/Ti interface into Al and N under the effect of Ti. As Ti has a strong affinity with N, the fast diffusion species N atoms will go into Ti, leading to the formation of TiN with Al in solid solution. The formation of TiN in the initial stage can be expressed by the following reactions, as shown in Fig. 8(a):

\[
\text{AlN} \rightarrow \text{Al} + \text{N} \quad \Delta G^0 = -159,770 \text{ (J/mole)}
\]

(1)

\[
\text{Ti} + \text{N} \rightarrow \text{TiN} \quad \Delta G^0 = -188,108 \text{ (J/mole)}
\]

(2)

\[
\text{AlN} + \text{Ti} \rightarrow \text{TiN} + \text{Al} \quad \Delta G^0 = -347,878 \text{ (J/mole)}
\]

(3)

(B) Second Stage: Formation of Ti3AlN and Various Titanium Aluminides: When the concentrations of Al and N increase to a certain amount, \(\tau_1\)-Ti3AlN is formed, as shown in Fig. 8(b), at the interface of TiN/Ti according to the following reaction:

\[
3\text{Ti} + \text{Al} + \text{N} \rightarrow \tau_1\text{-Ti}_3\text{AlN}
\]

(4)

The formation of \(\tau_1\)-Ti3AlN instead of \(\tau_2\)-Ti2AlN at this stage is consistent with the fact that \(\tau_1\)-Ti3AlN was found after annealing at 1300°C/0.5 h, which was at a relatively early stage. Meanwhile, excess Al and N atoms further go into Ti as a solid solution, leading to the formation of various titanium aluminonitrides, for example, \(\alpha\)-Ti(Al,N) and the \(\alpha\)-Ti(Al,N)+\(\beta\)-Ti(Al,N) two-phase region.

(C) Third Stage: Formation of Ti2AlN: As shown in Fig. 8(c), \(\tau_2\)-Ti2AlN is formed at this stage. The growth of the \(\tau_2\)-Ti2AlN was controlled by the diffusion of Al and N through TiN, accumulating at the TiN/\(\tau_1\)-Ti3AlN interface, leading to the disappearance of \(\tau_1\)-Ti3AlN based upon the following reaction:

\[
\tau_1\text{-Ti}_3\text{AlN} + \frac{1}{2}\text{Al} + \frac{1}{4}\text{N} \rightarrow \frac{3}{2}\tau_2\text{-Ti}_2\text{AlN}
\]

(5)

(D) Fourth Stage: Formation of \(\alpha\)-Ti2Al and/or the Two-Phase Layer (\(\alpha\)-Ti2Al/\(\alpha\)-Ti) During Cooling: Figure 8(d) shows that the \(\alpha\)-Ti(Al,N)+\(\beta\)-Ti(Al,N) two-phase region was transformed into the \(\alpha\)-Ti2Al/\(\alpha\)-Ti two-phase layer, while the \(\alpha\)-Ti(Al,N) layer was transformed into the \(\alpha\)-Ti2Al layer during cooling, depending upon the local composition. Not shown in Fig. 8(d) is that the \(\beta\)-Ti(Al,N) was transformed into the \(\alpha\)-Ti(Al,N). The phase transformations mentioned above can be expressed by the following reactions,

\[
\beta\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti(Al,N)}
\]

(6)

\[
\alpha\text{-Ti(Al,N)} + \beta\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti(Al,N)} + \alpha\text{-Ti}_2\text{Al(N)}
\]

(7)

\[
\alpha\text{-Ti(Al,N)} \xrightarrow{\text{cooling}} \alpha\text{-Ti}_2\text{Al(N)}
\]

(8)
IV. Conclusions

1. An interfacial reaction zone, consisting of TiN, \(\gamma\)-Ti\(_2\)AlN, \(\alpha\)-Ti\(_2\)AlN, and a two-phase \((\gamma\)-Ti\(_2\)AlN+\(\alpha\)-Ti\) region in sequence, was observed in between AlN and Ti after annealing at 1300 °C.

2. After annealing at 1300 °C, a textured structure existed in the \(\gamma\)-Ti\(_2\)AlN layer probably because of the internal stresses resulting from the mismatch in the thermal expansion coefficient between AlN and Ti. The fine equiaxed \(\gamma\)-Ti\(_2\)Al grains implied the occurrence of recrystallization. The orientation relationship between the equiaxed and elongated \(\gamma\)-Ti\(_2\)Al was as follows: \([0001]_{\text{equiaxed}}//[1100]_{\text{elongated}}\) and \([0101]_{\text{equiaxed}}//[1122]_{\text{elongated}}\).

3. In the two-phase \((\gamma\)-Ti\(_2\)AlN+\(\alpha\)-Ti\) region after annealing at 1300 °C, \(\gamma\)-Ti\(_2\)AlN and \(\alpha\)-Ti were found to satisfy the following orientation relationship: \([0001]_{\gamma\text{-Ti}_2\text{AlN}}//[0001]_{\gamma\text{-Ti}_2\text{AlN}}\) and \([1100]_{\gamma\text{-Ti}_2\text{AlN}}//[1100]_{\gamma\text{-Ti}_2\text{AlN}}\). The a value of \(\gamma\)-Ti\(_2\)Al was approximately twice that of \(\gamma\)-Ti.

4. The \(\gamma\)-Ti\(_2\)Al and a lamellar two-phase \((\gamma\)-Ti\(_2\)AlN+\(\alpha\)-Ti\)Al) structure were found in between \(\gamma\)-Ti\(_2\)AlN and \(\alpha\)-Ti\(_2\)AlN after annealing at 1400 °C. The orientation relationship of \(\gamma\)-Ti\(_2\)Al and \(\gamma\)-Ti\(_2\)AlN in the lamellar structure was identified to be as follows: \([2\overline{4}2\overline{3}]_{\gamma\text{-Ti}_2\text{AlN}}//[012]_{\text{TAI}}\) and \([1\overline{0}1\overline{0}]_{\gamma\text{-Ti}_2\text{AlN}}/[1\overline{0}0]_{\text{TAI}}\). Compared with the results after the reaction at 1400 °C, \(\gamma\)-Ti\(_2\)Al was not formed at the interface after the reaction at 1500 °C.

5. The diffusion path, connecting the phases formed by the reaction between AlN and Ti, was drawn on the Ti-Zr-O ternary phase diagram. Furthermore, the relationships among the Ti-Al-N ternary phase diagram, a modified binary phase diagram, and the microstructural development between AlN and Ti at 1300 °C and subsequent cooling have been proposed.
