The mechanism for the reaction Cl + ClOOC1 has been investigated by ab initio molecular orbital and transition-state theory calculations. The result shows that the reaction can produce both Cl₂ + ClOO and Cl₂O + ClO. The former product pair can be formed by direct and indirect abstraction paths. The direct abstraction path, which dominates at low temperatures, takes place barrierlessly with the rate constant \( k_1 = 1.53 \times 10^{-13} \exp(118/T) \) cm³ molecule⁻¹ s⁻¹ in the temperature range of 200–1000 K. The rate constant of the indirect path, which occurs via the two isomers of the Cl–O(Cl)OCl complex lying 3 kcal/mol below the reactants, \( k'_1 = 7.14 \times 10^{-12} T^{0.86} \exp(-2370/T) \) cm³ molecule⁻¹ s⁻¹, accounting for less than 0.1% of the Cl₂ yield at 298 K but increasing to about 46% at 1000 K. The new Cl₂O + ClO products can be produced by the fragmentation of the two complexes; the rate constant for their formation was found to be pressure-independent and can be expressed by \( k_2 = 2.19 \times 10^{-14} T^{0.70} \exp(-1110/T) \) cm³ molecule⁻¹ s⁻¹ covering the temperature range of 200–1000 K. Above room temperature, Cl₂O formation becomes competitive; for example, its branching ratios, \( k_2/k_1 \), are predicted to be 0.19, 0.55, and 0.62 at 298, 500, and 1000 K, respectively. The predicted total rate constant agrees closely with available experimental results. The heat of formation of ClOOC1 has been examined in detail using different reactions and computational methods. The results of these calculations converge to \( \Delta H^0_0(\text{ClOOC1}) = 30 \pm 2 \) kcal/mol.

I. Introduction

Chlorine peroxide (ClOOC1), formed by the recombination of ClO radicals, plays a pivotal role in the O₃-destruction chemistry.\(^1\)–\(^3\) Its photodissociation reaction in the stratosphere regenerates Cl atoms and, to some extent, ClO radicals depending\(^4\)–\(^9\) on the wavelength.\(^4\)–\(^9\) The reaction of ClOOC1 with Cl is known to be very fast with the production of Cl₂ and ClOO exclusively.\(^10\)–\(^11\)

\[
\text{Cl} + \text{ClOOC1} \rightarrow \text{Cl}_2 + \text{ClOO}
\]  

(1)

In principle, another exothermic product pair, Cl₂O + ClO, could be formed and possibly quite competitively because two stable molecular complexes between Cl and ClOOC1 were found to exist in our recent study of the reaction (vide infra). The formation of the complex might help promote the following reaction:

\[
\text{Cl} + \text{ClOOC1} \rightarrow \text{Cl} \cdots \text{O(Cl)OCl} \rightarrow \text{Cl}_2 \text{O} + \text{ClO}
\]  

(2)

The objective of this study is to predict the relative contribution of the two product channels on the basis of ab initio molecular orbital and statistical rate constant calculations, which have been shown to be quite useful in estimating total rate constants and product branching ratios as well for several complex ClO₃ reactions in this laboratory.\(^12\)–\(^15\)

II. Computational Methods

The geometries of the reactants, intermediates, transition states, and products of the Cl + ClOOC1 reaction are computed at the G96LYP/6-311+G(3df) level with Barone and Adamo’s Becke-type one-parameter functional using Gill96 exchange and LYP correlation.\(^16\) Vibrational frequencies employed to characterize stationary points and zero-point energy (ZPE) corrections have also been calculated at this level of theory and have been used for the rate constant calculations. Intrinsic reaction coordinate (IRC) calculations\(^17\) have been performed to confirm the connection of each transition state with designated reactants and products.

The energies of all species were calculated by the G2M method,\(^18\) which uses a series of calculations with G96LYP/6-311+G(3df)-optimized geometries to approximate the CCSD(T)-F12A level of theory, including a “higher level correction (HLC)” based on the number of paired and unpaired electrons. All calculations were carried out with Gaussian 98.\(^19\)

The rate constants were computed with a microcanonical variational Rice–Ramsperger–Kassel–Marcus (RRKM) approach using the Variflex\(^20\) and ChemRate codes.\(^21\)

III. Results and Discussion

A. Potential Energy Surface and Reaction Mechanism.

For this reaction, the products are mainly produced via a doublet potential energy surface (PES). From the PES characteristics of the \(^3\)O + OCIO system,\(^14\) we have learned that the transition states on this type of doublet PES are sensitive to the methods employed. To obtain reliable transition states, we first optimized one transition state (TS5 in Figure 1) structure at the G96LYP/6-311+G(3df), PW91PW91/6-311+G(3df), MPW1PW91/6-311+G(3df), B3LYP/6-311+G(3df), and MP2/6-311+G(2d) levels of theory. The (S²) values determined by these methods are, correspondingly, 0.758, 0.760, 0.872, 0.847, and 1.565. The G2M barriers relative to the reactants based on these optimized
structures are 0.86, 1.71, 14.3, 14.6, and 8.4 kcal/mol, respectively. From our previous calculation, we noted that when an optimized molecular structure has a large $\langle S^2 \rangle$ value, it is difficult to obtain a reliable G2M energy; therefore, the MPW1PW91/6-311+G(3df), B3LYP/6-311+G(3df), and MP2/6-311+G(2d) methods, which gave greater $\langle S^2 \rangle$ values, were not used and only the G96LYP/6-311+G(3df) method was employed to optimize all other transition states or stable species for this reaction. However, we should note that the G2M(cc2)//G96LYP/6-311+G(3df) method does give reasonable heat of formation for the ClOOCl molecule, 33.9 (0.9 and 31.7 (0.7 kcal/mol based on the reactions Cl + ClOOCl $\rightarrow$ ClO + ClOCl and Cl + ClOOCl $\rightarrow$ Cl$_2$ + ClOO, respectively. These results are close to the experimental values, 29.7$^{22}$ and 32.6$^{11}$ kcal/mol and to our previously predicted value, 29.4 kcal/mol.$^{14}$

The PES and the heat of formation for ClOOCl predicted at the G2M(cc2)//G96LYP/6-311+G(3df) level of theory will be discussed below.

The optimized geometries of the intermediates and transition states for the reaction of Cl + ClOOCl are shown in Figure 1. The potential energy diagram obtained at the G2M/G96LYP/6-311+G(3df) level is presented in Figure 2. The vibrational frequencies and rotational constants are summarized in Table 1.

Formation of Cl$_2$ + ClOO Products. As discussed previously, among the five isomers of Cl$_2$O$_2$, the ClOOCl molecule with $C_2$ symmetry is most stable. Experimentally,$^{10,11}$ the Cl$_2$-formation channel was found to be fast and has been assumed to be the only channel for the reaction. However, no detailed discussion on the mechanism has been presented in the literature.
and can readily rotate; the interaction of Cl with Cl can produce Cl\(_2\) at 3.0 kcal/mol at the G2M level. The reaction of discussion. The two complexes have similar structural parameters (see Figure 1) except that their ClO\(^{+}\) bonds lengthen by about 0.35 Å in TS5 and TS6 compared with those in LM1 and LM2; the forming Cl−O\(^{+}\) bond lengths decrease from 2.835 and 2.631 Å in LM1 and LM2 to 2.319 and 2.320 Å in TS5 and TS6, respectively. At the G2M level, TS5 and TS6 lie above the reactants by 0.86 and 0.79 kcal/mol, respectively.

**Heat of Formation for ClOOCI.** Although the heat of formation for ClOOCI does not affect the predicted rate constants in the present case, because of its significant relevance to the stratospheric O\(_3\)-destruction chemistry, we have examined the heat of formation of ClOOCI in greater detail. Based on the experimental heats of formation\(^{23}\) for Cl, ClO, ClOCl, and ClOO and the predicted enthalpy changes for the two reactions

\[
\text{Cl} + \text{ClOOCl} &\rightarrow \text{Cl} + \text{ClOOCl}, \quad \Delta H^0 = -19.3 \text{ kcal/mol} \\
\text{Cl} + \text{ClOOCl} &\rightarrow \text{Cl} + \text{ClOO}, \quad \Delta H^0 = -37.8 \text{ kcal/mol}
\]

As shown in Figure 2, several reaction paths can lead to the abstraction products, Cl\(_2\) + ClOO.

**Direct Path.** In ClOOCI, the two O and the two Cl atoms are equivalent. In principle, Cl atom can attack one of the Cl or O in ClOOCI to form different products. Our ab initio results show that when the Cl atom attacks one of the Cl in ClOOCI, it directly leads to Cl\(_2\) + ClOO barrierlessly with the exothermicity of 37.8 kcal/mol at the G2M level.

**Indirect Path.** As shown in Figures 1 and 2, the attacking Cl atom can form two isomeric complexes (LM1 and LM2) with ClOOCI, which will be labeled as ClO\(^{+}\)O\(^{−}\)Cl\(^{+}\) for the convenience of discussion. The two complexes have similar structural parameters (see Figure 1) except that their ClO\(^{+}\)O\(^{−}\) dihedrals, 119.1° and −139.7°, indicate that Cl attacks the O\(^{−}\) atom from different directions. They lie below the reactants by 3.4 and 3.0 kcal/mol at the G2M level. LM1 can readily isomerize to LM2 via TS1 with a 1.9 kcal/mol barrier.

LM1, having the O−Cl bond length of 2.835 Å, is looser and can readily rotate; the interaction of Cl with Cl\(^{+}\) via TS2 can produce Cl\(_2\) + ClOO (ClCl\(^{+}\) + ClO\(^{+}\)O\(^{−}\)) with a barrier above the reactants by 3.5 kcal/mol. In LM2, besides the possible interaction of Cl with Cl\(^{+}\) to eliminate ClCl\(^{+}\) via TS3 (with a barrier above the reactants by 3.4 kcal/mol), the Cl atom can also interact with Cl\(^{+}\) to form ClCl\(^{+}\) + ClO\(^{+}\)O\(^{−}\) via TS4 with a barrier above the reactants by 2.8 kcal/mol (see Figures 1 and 2).

**Formation of ClOOCI + ClOO Products.** As discussed in the above section, the reaction of Cl with ClOOCI can form two complexes, LM1 and LM2, which can not only undergo elimination of ClCl\(^{+}\) or ClCi\(^{+}\) but also dissociate to give ClO\(^{+}\)Cl\(^{+}\) + ClO\(^{−}\) via the corresponding transition states TS5 and TS6. Similar to those of LM1 and LM2, the apparent difference in structural parameters of TS5 and TS6 lies in the ClO\(^{+}\)Cl\(^{+}\) dihedrals, 136.7° and −136.9°, respectively. The breaking O\(^{−}\)O\(^{+}\) bonds lengthen by about 0.35 Å in TS5 and TS6 compared with those in LM1 and LM2; the forming Cl−O\(^{+}\) bond lengths decrease from 2.835 and 2.631 Å in LM1 and LM2 to 2.319 and 2.320 Å in TS5 and TS6, respectively. At the G2M level, TS5 and TS6 lie above the reactants by 0.86 and 0.79 kcal/mol, respectively.

\rightarrow Cl\textsubscript{2} (ClCl\textsuperscript{'}\textsuperscript{'}) + ClOO (Cl'OO)  
\rightarrow LM1\textsuperscript{*} \rightarrow Cl + ClOOC\textsubscript{2}  
\rightarrow ClO + ClOCl  
\rightarrow Cl\textsubscript{2} (ClCl\textsuperscript{'}\textsuperscript{'}) + ClOO (Cl'OO)  
\rightarrow LM1 (+M)

where * denotes the chemically activated LM1 or LM2. The energies plotted in Figure 2 and the vibrational frequencies and rotational constants listed in Table 1 were used in the calculation. Because the product formation processes were found to be pressure-independent, the Lennard-Jones (L-J) parameters required for the stabilization of ClO(Cl)OCl (LM1\textsubscript{a} and LM2\textsubscript{a}) were assumed to be approximately the same as that of ClOOC\textsubscript{2}\textsuperscript{14b}.

\textit{Cl\textsubscript{2} + ClO\textsubscript{2} Formation.} As alluded to in the preceding discussion on the results of ab initio calculations, Cl\textsubscript{2} + ClOO can be directly and indirectly formed. The initial association process does not have a well-defined transition state because of the absence of an intrinsic reaction barrier. In this case, the ClO\textsubscript{2}/ClO\textsubscript{2} complex on the Cl\textsubscript{2} + ClOO side was first located, and then Cl\textsubscript{2}/ClO\textsubscript{2} was dissociated to produce ClOCl via TS2, TS3, and TS4 with barriers of 3.5, 3.4, and 2.8 kcal/mol above the reactants, the smallest frequency vibration (less than 50 cm\textsuperscript{-1}) in these TSs was treated as a free rotation and the reduced moment of inertia was approximately determined to be 207.1 amu. The sum of the rate constants for these indirect Cl\textsubscript{2}-formation paths, \(k_1\), shown as a dashed—dotted line in Figure 3, is minor at room temperature, amounting to less than 0.1% of Cl\textsubscript{2} yield at 298 K, but it increases to about 46% at 1000 K. The indirect abstraction rate constant for the formation of Cl\textsubscript{2} + ClOO can be expressed as \(k_1 = 7.14 \times 10^{-127}T^{1.1} \exp(-2370/T)\) cm\textsuperscript{3} molecule\textsuperscript{-1} s\textsuperscript{-1} in the temperature range of 200–1000 K.

\textit{ClO + ClOCl Formation.} Besides the above paths, LM1\textsubscript{a} and LM2\textsubscript{a} can also dissociate to produce ClO + ClOCl via TS5 and TS6. The vibration with the smallest frequency in these two transition states was also treated as a free internal rotator, and the reduced moment of inertia was determined to be 1124 amu. The predicted rate constant of Cl\textsubscript{2} + ClOO, \(k_1\), and \(k_2\) respectively. Dashed line represents \(k_2\) for ClO + ClOCl formation, and the thick solid line represents the total rate constant. Symbols are experimental data of ref 11.

**Figure 3.** Comparison of the predicted rate constants with the experimental values in N\textsubscript{2}. Dotted and dashed—dotted lines represent the predicted formation rate constants of Cl\textsubscript{2} + ClOO, \(k_1\) and \(k_2\), respectively. Dashed line represents \(k_2\) for ClO + ClOCl formation, and the thick solid line represents the total rate constant. Symbols are experimental data of ref 11.
At lower temperatures, the direct abstraction channel forming ClOCl products becomes quite significant and competitive. The available experimental data\textsuperscript{10,11,29} in which Cl\textsubscript{2} + ClO becomes very competitive. The predicted total rate constant is in reasonable agreement with ClOCl becoming quite significant and competitive. The total rate constant experimentally determined for ClOO is dominant; over 298 K, formation of ClO + ClOO becomes very competitive.
