Abstract

Zuo claimed that the comparison of Birnbaum importance between two components for a consecutive-\(k\)-out-of-\(n\):\(G\) system is the same as that for the \(F\)-system. We show that this is not the case and give a correct relation between the two systems.

Keywords: Consecutive-\(k\)-out-of-\(n\) system; Reliability; Birnbaum importance

1. Introduction

A consecutive-\(k\)-out-of-\(n\):\(F\) system, denoted by \(L(k, n:F)\), is a line of \(n\) components such that the system fails if some \(k\) consecutive components all fail. Similarly, we can define a consecutive-\(k\)-out-of-\(n\):\(G\) system, denoted by \(L(k, n:G)\) as a line of \(n\) components such that the system works if some \(k\) consecutive components all work. The reliability of \(L(k, n:M), M \in \{F, G\}\), is denoted by \(R(k, n:M)\).

Zuo [3] claimed that the Birnbaum importance [4] of component \(i\) for a consecutive-\(k\)-out-of-\(n\):\(G\) system is the same as that for the \(F\)-system. We show that this is not the case and give a correct relation between the two systems.

In this article, we show that the claim is wrong. We also give a correct relation.

2. The interplay between \(F\)-systems and \(G\)-systems

The Birnbaum importance of component \(i\) in a system \(S\) is defined as,

\[ I_i(S) = R(S \mid i \text{ working}) - R(S \mid i \text{ failed}). \]

Zuo [3] claimed that

\[ I_i(L(k, n:F)) = I_i(L(k, n:G)), \]

\[ I_i(L(k, n:F)) \equiv I_i(L(k, n:F)) \]

\[ \iff I_i(L(k, n:G)) \equiv I_i(L(k, n:G)) \]

(Note that \(1 \implies 2\)).

For the i.i.d. case, we will include \(p\) as a parameter in the importance function.

Papastavridis [2] proved

Lemma 1.

\[ I_i(L(k, n:F, p)) = \frac{R(k, i - 1:F, p)R(k, n - i:F, p) - R(k, n:F, p)}{q}. \]
Kuo et al. [1] proved

**Lemma 2.**

\[
I_i(L(k, n; G, p)) = \frac{\overline{R}(k, i - 1; G, p)\overline{R}(k, n - i; G, p) - \overline{R}(k, n; G, p)}{p}.
\]

By noting that \(\overline{R}(k, n; G, p) = R(k, n; F, q)\) for all \(n\), we have

**Corollary 3.**

\[
I_i(L(k, n; G, p)) = \frac{R(k, i - 1; F, q)\overline{R}(k, n - i; F, q) - R(k, n; F, q)}{p}
\]

\[
= I_i(L(k, n; F, q)).
\]

By not including parameter \(p\) in the importance function, Zuo [3] misinterpreted Corollary 3 as

\[
I_i(L(k, n; G)) = I_i(L(k, n; F))
\]

and made claim (1). Then he used claim (1) to prove claim (2).

**Corollary 4.**

\[
I_i(L(k, n; G, p)) - I_i(L(k, n; G, p))
\]

\[
= I_i(L(k, n; F, q)) - I_i(L(k, n; F, q)).
\]

Therefore, if the comparison of \(I_i\) and \(I_i\) depends on \(p\), in particular, if the sign of their difference can vary with \(p\), then claim (2) will not hold. That this, is indeed the case will be illustrated by a specific example (the smallest in terms of \(k\) and \(n\)) in Section 3.

**3. A specific counter-example**

Let \(n = 7\) and \(k = 3\). Then,

\[
\Delta(p) \equiv I_2(L(3, 7; F, p)) - I_4(L(3, 7; F, p))
\]

\[
= [R(3, 1; F, p)R(3, 5; F, p)] - R(3, 3; F, p)R(3, 3; F, p)/q
\]

\[
= (p - 6p^3 + 13p^5 + 6p^7 - p^9)/q
\]

\[
= p(1 - p)^2(1 - 3p + p^2).
\]

It is easily verified that between 0 and 1, \(\Delta(p)\) changes sign once at around \(p = 0.38\). Therefore \(\Delta(0.2) > 0 > \Delta(0.8)\). It follows,

\[
I_2(L(3, 7; F, 0.2)) > I_4(L(3, 7; F, 0.2)),
\]

\[
I_2(L(3, 7; F, 0.8)) < I_4(L(3, 7; F, 0.8)).
\]

By Corollary 4, the first inequality implies

\[
I_2(L(3, 7; G, 0.8)) > I_4(L(3, 7; G, 0.8)).
\]

The curve of \(\Delta(p)\) is given in Fig. 1. We conjecture that \(\Delta(p)\) changes sign at most once between 0 and 1. One would hope that \(I_i\) have some good property, such as convexity. But this is not the case. For example,

![Fig. 1. The curve of \(I_2(L(3, 7; F, p)) - I_4(L(3, 7; F, p)).\)](image-url)
Thus,
\[ I_1(L(3, 7:F, p)) = pq^7(1 - q^3) = 3p^2 - 9p^3 + 10p^4 - 5p^5 + p^6. \]

Since \( \frac{\partial^2 I_1}{\partial p^2} = 6 - 54p + 120p^2 - 100p^3 + 30p^4 > 0 \) for \( p \) small, \( I_1 \) is not convex (nor is it concave since the second derivative is negative around \( p = 0.38 \)).

Zuo and Kuo [5] proved that the importance ranking of components in the consecutive-2 \( G \)-line is same as in the consecutive-2 \( F \)-line. The counter-example given here showed that this conclusion cannot be extended to general \( k \).
