Let S be a connected graph which contains an induced path of n − 1 vertices, where n is the order of S. We consider a puzzle on S. A configuration of the puzzle is simply an n-dimensional column vector over {0, 1} with coordinates of the vector indexed by the vertex set S. For each configuration u with a coordinate u s = 1, there exists a move that sends u to the new configuration which flips the entries of the coordinates adjacent to s in u. We completely determine if one configuration can move to another in a sequence of finite steps.

1. Introduction

Let S be a simple connected graph with vertex set \( S = \{s_1, s_2, \ldots, s_n\} \). By a flipping puzzle on S, we mean a set of configurations of S and a set of moves on the configurations defined below. The configuration of the flipping puzzle is S, together with an assignment of white or black state to each vertex of S. A move applied to a configuration u in the puzzle is to select a vertex \( s_i \) which has a black state, and then flip the states of all neighbors of \( s_i \) in u. For convenience we use the set \( F_2^n \) of column vectors over \( F_2 := \{0, 1\} \), coordinates indexed by S, to denote the set of configurations of S. Precisely, for a configuration \( u \in F_2^n, u_{s_i} = 1 \) iff u has a black state in the vertex \( s_i \). Then for a configuration u with \( u_{s_i} = 1 \) for some \( s_i \in S \), we can apply a move to u by changing u into \( u + \tilde{A}_{s_i} \), where \( \tilde{A}_{s_i} \) is the column indexed by \( s_i \) in the adjacency matrix A of S. A flipping puzzle is also called a lit-only \( \sigma \)-game in [19]. The study of flipping puzzles is related to the representation theory of Coxeter groups [8] and Lie algebras [1,2,4,5,11].

Two configurations in the flipping puzzle on S are said to be equivalent if one can be obtained from the other by a sequence of selected moves. Let \( \mathcal{P} \) denote the partition of \( F_2^n \) according to the above equivalent relation. A general question in solving the flipping puzzle on S is to realize that for a given
pair of configurations \( u, v \in F_2^n \), whether \( v \) can be obtained from \( u \) by a sequence of selected moves or not. This can be done if \( \mathcal{P} \) is completely determined.

In this paper we are mainly concerned about the class of graphs, each of which contains an induced path on \( \{s_1, s_2, \ldots, s_{n-1}\} \). This class of graphs includes the simply-laced Dynkin diagrams and simply-laced extended Dynkin diagrams with exceptions \( \tilde{D}_n \) and \( \tilde{E}_6 \). In each case of such graphs we determine \( \mathcal{P} \).

For \( u \in F_2^n \) let
\[
w(u) := |\{s_i \in S \mid u_{s_i} = 1\}|
\]
denote the Hamming weight of \( u \), and for an orbit \( O \in \mathcal{P} \),
\[
w(O) := \min\{w(u) \mid u \in O\}
\]
is called the weight of the orbit \( O \). The number
\[
M(S) := \max\{w(O) \mid O \in \mathcal{P}\}
\]
is called the maximum-orbit-weight of the graph \( S \). A consequence of our result on \( \mathcal{P} \) we find \( M(S) \leq 2 \) and we give a necessary and sufficient condition for \( M(S) = 1 \). We also determine the cardinality of \( \mathcal{P} \). A summary of our results is given in a table of Section 7. Besides these results, a byproduct is Theorem 3.9.

If \( S \) is a tree with \( \ell \) leaves, Wang, Wu [19] and Wu, Chang [20] independently prove \( M(S) \leq \lceil \ell/2 \rceil \). For each case of Dynkin diagrams and extended Dynkin diagrams, \( \mathcal{P} \) is completely determined by Chuah and Hu [4,5]. The study of flipping puzzles is related to a rich research subject called “groups generated by transvections”. We will provide this connection in Appendix.

2. Matrices representing the puzzle

Let \( S \) be a simple connected graph with \( n \) vertices. Let \( F_2 \) denote the 2-element finite field with addition identity 0 and multiplication identity 1, and let \( F_2^n \) denote the set of \( n \)-dimensional column vectors over \( F_2 \) indexed by \( S \). We shall embed the graph \( S \) in \( F_2^n \) canonically. For \( s \in S \), let \( \tilde{s} \) denote the characteristic vector of \( s \) in \( F_2^n \); that is \( \tilde{s} = (0, 0, \ldots, 0, 1, 0, \ldots, 0)^t \), where 1 is in the position corresponding to \( s \). The set \( \{\tilde{s} \mid s \in S\} \) is called the standard basis of \( F_2^n \). In this setting, for \( T \subseteq S \) the vector
\[
\sum_{s \in T} \tilde{s}
\]
represents the configuration with black states in \( T \) in the flipping puzzle on \( S \) as stated in the introduction. We shall assign each move as an \( n \times n \) matrix that acts on \( F_2^n \) by left multiplication. Let \( \text{Mat}_n(F_2) \) denote the set of \( n \times n \) matrices over \( F_2 \) with rows and columns indexed by \( S \).

**Definition 2.1.** For \( s \in S \), we associate a matrix \( s \in \text{Mat}_n(F_2) \), denoted by the bold type of \( s \), as
\[
s_{ab} = \begin{cases} 
1, & \text{if } a = b, \text{ or } b = s \text{ and } ab \in R; \\
0, & \text{else},
\end{cases}
\]
where \( a, b \in S \) and \( R \) is the edge set of \( S \). The matrix \( s \) is called the flipping move associated with vertex \( s \).

It is easy to check that for \( s, b \in S \),
\[
s\tilde{b} = \left\{ \begin{array}{ll}
\tilde{b}, & \text{if } b \neq s; \\
\tilde{b} + \sum_{ab \in R} \tilde{a} & \text{if } b = s.
\end{array} \right.
\]
Hence if a configuration \( u \in F_2^n \) with \( u_s = 1 \) then \( su \) is the new configuration after the move to select the vertex \( s \). Note that if \( u_s = 0 \), we have \( su = u \), so we can view the action of \( s \) on \( u \) as a feigning move on \( u \) which is not originally defined as a move in the flipping puzzle. Note that \( s \) is an involution and hence is invertible for \( s \in S \).
Definition 2.2. Let \( W \) denote the subgroup of \( \text{GL}_n(F_2) \) generated by the set \( \{ s \mid s \in S \} \) of flipping moves. \( W \) is called the \textit{flipping group} of \( S \).

The flipping groups of simply-laced Dynkin diagrams are studied in [8]. The flipping group of the line graph of a tree with \( n \) vertices is isomorphic to the symmetric group \( S_n \) on \( n \) elements if \( n \geq 3 \) [21]. However, we do not need the information of the flipping group \( W \) of \( S \) in this paper.

3. The sets \( \Pi, \Pi_0 \) and \( \Pi_1 \)

For the remaining of the paper, the following assumption is assumed.

Assumption 3.1. Let \( S \) be a simple connected graph with \( n \) vertices \( s_1, s_2, \ldots, s_n \), and suppose that the sequence \( s_1, s_2, \ldots, s_{n-1} \) is an induced path, among them, \( s_{j_1}, s_{j_2}, \ldots, s_{j_m} \) the neighbors of \( s_n \), where \( 1 \leq j_1 < j_2 < \cdots < j_m \leq n - 1 \). See Fig. 1.

In the remaining of this paper, we always assume \( n \geq 2 \) and set

\[
\tilde{1} = \tilde{s}_1, \quad \tilde{i} + 1 = s_is_{i-1} \cdots s_1 \tilde{1} \quad \text{for} \quad 1 \leq i \leq n - 1.
\]

(3.1)

Set

\[
\Pi = \{ \tilde{1}, \tilde{2}, \ldots, \tilde{n} \},
\]

(3.2)

\[
\Pi_0 = \{ \tilde{i} \in \Pi \mid \langle i, \tilde{s}_n \rangle = 0 \},
\]

(3.3)

\[
\Pi_1 = \Pi - \Pi_0,
\]

(3.4)

where \( \langle , \rangle \) is the dot product of vectors. From (3.1) and the construction,

\[
\Pi_0 = \{ \tilde{i} \mid \tilde{i} = \tilde{s}_{i-1} + \tilde{s}_1, \quad 1 \leq i \leq n - 1 \text{ or } \tilde{i} = \tilde{s}_{n-1} \},
\]

(3.5)

\[
\Pi_1 = \{ \tilde{i} \mid \tilde{i} = \tilde{s}_{i-1} + \tilde{s}_1 + \tilde{s}_n, \quad 1 \leq i \leq n - 1 \text{ or } \tilde{i} = \tilde{s}_{n-1} + \tilde{s}_n \},
\]

(3.6)

where \( \tilde{s}_0 = 0 \). Note that \( 1 \leq |\Pi_0|, |\Pi_1| \leq n - 1 \) and \( |\Pi_0| + |\Pi_1| = n \). Precisely,

\[
\Pi_0 = \{ \tilde{i} \in \Pi \mid i \in \{0, j_1\} \cup \{j_2, j_3\} \cup \cdots \cup \{j_{2k}, j_{2k+1}\} \}
\]

(3.7)

\[
\Pi_1 = \{ \tilde{i} \in \Pi \mid i \in \{j_1, j_2\} \cup \{j_3, j_4\} \cup \cdots \cup \{j_{2k-1}, j_{2k}\} \}
\]

(3.8)

where \( k = \left\lceil \frac{n}{2} \right\rceil, j_t := n \) if \( t > m \) and \( \{a, b\} = \{x \mid x \in \mathbb{Z}, a < x \leq b \} \). In particular we have the following proposition.

Proposition 3.2.

\[
|\Pi_1| = \sum_{k=1}^{\left\lceil \frac{n}{2} \right\rceil} j_{2k} - j_{2k-1}. \quad \Box
\]
From (3.5) and (3.6), we immediately have the following lemma.

**Lemma 3.3.** For $1 \leq i \leq n - 1$,

$$\bar{1} + \bar{2} + \ldots + \bar{i} = \begin{cases} \bar{s}_i + \bar{s}_n, & \text{if } |[\bar{i}] | \cap [\Pi_1] \text{ is odd}; \\ \bar{s}_i, & \text{if } |[\bar{i}] | \cap [\Pi_1] \text{ is even}, \end{cases}$$

and

$$\bar{1} + \bar{2} + \ldots + \bar{n} = \begin{cases} \bar{s}_n, & \text{if } |[\Pi_1] | \text{ is odd}; \\ 0, & \text{if } |[\Pi_1] | \text{ is even}, \end{cases}$$

where $[\bar{i}] := \{1, 2, \ldots, \bar{i}\}$. □

From Lemma 3.3 and (3.7) we have the following lemma.

**Lemma 3.4.** $\sum_{i \in \Pi_0} \bar{i} = \sum_{k=1}^m \bar{s}_k$.$\quad$□

From (3.1) we have the following lemma.

**Lemma 3.5.** $s_i \bar{i} = \bar{i} + 1$, $s_i \bar{i} + 1 = \bar{i}$ and $s_i$ fixes other vectors in $\Pi - \{\bar{i}, \bar{i} + 1\}$ for $1 \leq i \leq n - 1$. □

From Lemma 3.5, $s_i$ acts on $\Pi$ as the transposition $(\bar{i}, \bar{i} + 1)$ in the symmetric group $S_n$ of $\Pi$ for $1 \leq i \leq n - 1$. Let $W$ denote the flipping group of $S$. By a $W$-submodule of $F^n_2$ we mean a subspace $U$ of $F^n_2$ such that $WU \subseteq U$.

**Corollary 3.6.** The subspace $U$ spanned by the vectors in $\Pi$ is a $W$-submodule of $F^n_2$.

**Proof.** From Lemma 3.5, $U$ is closed under the action of $s_1, s_2, \ldots, s_{n-1}$. Note that for $\bar{i} \in \Pi$ we have

$$s_n \bar{i} = \begin{cases} \bar{i}, & \text{if } \bar{i} \in \Pi_0; \\ \bar{i} + \sum_{j \in \Pi_0} j, & \text{if } \bar{i} \in \Pi_1 \end{cases} \in U$$

by Lemma 3.4. □

**Proposition 3.7.** The subspace $U$ in Corollary 3.6 has the basis

$$\begin{cases} \Pi, & \text{if } |\Pi_1| \text{ is odd}; \\ \Pi - \{\bar{j}\}, & \text{if } |\Pi_1| \text{ is even} \end{cases}$$

for any $\bar{j} \in \Pi$. Moreover $\bar{s}_n \not\in U$ if $|\Pi_1| \text{ is even}$. □

**Proof.** By Lemma 3.3, $\bar{1}, \bar{2}, \ldots, \bar{n-1}$ are linearly independent and hence $U$ has dimension at least $n - 1$. Since $\bar{s}_n \not\in \text{Span}\{1, 2, \ldots, n - 1\}$, the proposition follows from the second case of Lemma 3.3. □

Let $W_p$ denote the subgroup of $W$ generated by $s_1, s_2, \ldots, s_{n-1}$. From Lemma 3.5, Proposition 3.7 and the fact $G_{S_n} = \bar{s}_n$ for $G \in W_p$, we have the following corollary.

**Corollary 3.8.** The subgroup $W_p$ of $W$ is isomorphic to the symmetric group $S_n$ on $\Pi$. □

Let $S'$ be another graph satisfying Assumption 3.1, $s'_n$ be the corresponding matrix in Definition 2.1 and $\Pi', \Pi'_0, \Pi'_1$ be the corresponding sets of vectors in (3.2)-(3.4). For this moment we suppose $|\Pi_1| = |\Pi'_1|$. Let $f : \Pi \cup \{\bar{s}_n\} \to \Pi' \cup \{\bar{s}'_n\}$ be a bijection such that $f(\bar{s}_n) = \bar{s}'_n$ and $f(\Pi_1) = \Pi'_1$. Then

$$s'_n f(\bar{s}_n) = f(\bar{s}_n) + \sum_{j \in \Pi_0} f(\bar{j})$$
and
\[ s_n f(i) = \begin{cases} f(i), & \text{if } i \in \Pi_0; \\ f(i) + \sum_{j \in \Pi_0} f(j), & \text{if } i \not\in \Pi_0 \end{cases} \]
are corresponding to the way that \( s_n \) acts on \( \Pi \cup \{\tilde{s}_n\} \). From Corollary 3.8 and the above arguments we have the following theorem.

**Theorem 3.9.** \( W \) is unique up to isomorphism among all the graphs satisfying Assumption 3.1 with a given cardinality \(|\Pi_1|\) computed from (3.2). □

The flipping group \( W \) of a simply-laced Dynkin diagram \( S \) is isomorphic to the quotient group \( W/Z(W) \) of the Coxeter group \( W \) of \( S \) by its center \( Z(W) \) [8], and the study of Coxeter groups \( W \) is notoriously interesting. With this in mind, one might expect the flipping groups are very different on different graphs. Theorem 3.9 is surprising since up to isomorphism the number of flipping groups is at most \( n-1 \), which is much less than the number of graphs satisfying Assumption 3.1.

### 4. Simple basis \( \Delta \) of \( F_n^2 \)

To better describe the orbits in \( \mathcal{P} \) later, we need to choose a new basis of \( F_n^2 \). Set
\[ \Delta := \begin{cases} \Pi, & \text{if } |\Pi_1| \text{ is odd}; \\ \Pi \cup \{\bar{n}+1\} - \{\bar{n}\}, & \text{if } |\Pi_1| \text{ is even}, \end{cases} \]
where \( \bar{n}+1 := \tilde{s}_n \). With referring to Proposition 3.7, \( \Delta \) is a basis of \( F_n^2 \). To distinguish from the standard basis \( \{\tilde{s}_1, \tilde{s}_2, \ldots, \tilde{s}_n\} \) of \( F_n^2 \), we refer \( \Delta \) to the simple basis of \( F_n^2 \). For each vector \( u \in F_n^2 \), \( u \) can be written as a linear combination of elements in \( \Delta \), so let \( \Delta(u) \) be the subset of \( \Delta \) such that
\[ u = \sum_{i \in \Delta(u)} i, \]
set \( sw(u) := |\Delta(u)| \), and we refer \( sw(u) \) to be the simple weight of \( u \). Note that for \( 1 \leq i \leq n-1 \), the vector \( 1+2+\cdots+i \) has simple weight \( i \), but has weight
\[ w(1+2+\cdots+i) = \begin{cases} 1, & \text{if } |\{i\} \cap \Pi_1| \text{ is even}; \\ 2, & \text{if } |\{i\} \cap \Pi_1| \text{ is odd} \end{cases} \]
by Lemma 3.3.

The following notation will be used in the sequel. For \( V \subseteq F_n^2 \) and \( T \subseteq \{0, 1, \ldots, n\} \),
\[ V_T := \{u \in V \mid sw(u) \in T\}, \]
and for shortness \( V_{t_1, t_2, \ldots, t_i} := V_{\{t_1, t_2, \ldots, t_i\}} \). Let \( odd \) be the subset of \( \{1, 2, \ldots, n\} \) consisting of odd integers.

### 5. The case \(|\Pi_1| \text{ is odd}\)

In this section we assume \(|\Pi_1| \) to be odd and the counter part is treated in the next section. Note that \( \Delta = \{\bar{1}, \bar{2}, \ldots, \bar{n}\} \) is a basis of \( U = F_n^2 \) in this case. From Lemma 3.3, for \( 1 \leq i \leq n-1 \),
\[ \tilde{s}_i = \begin{cases} \bar{1}+\bar{2}+\cdots+\bar{i}, & \text{if } |\{i\} \cap \Pi_1| \text{ is even}; \\ i+1+i+2+\cdots+\bar{n}, & \text{if } |\{i\} \cap \Pi_1| \text{ is odd}, \end{cases} \]
and
\[ \tilde{s}_n = \bar{1}+\bar{2}+\cdots+\bar{n}. \]
Hence, for $1 \leq i \leq n - 1$,
\[
sw(\tilde{S}_i) = \begin{cases} i, & \text{if } |[i] \cap I_1| \text{ is even;} \\ n - i, & \text{if } |[i] \cap I_1| \text{ is odd,} \end{cases}
\]
and $sw(\tilde{S}_n) = n$. In other words, there exists a vector with simple weight $i$ and weight $1$ if and only if $|[i] \cap I_1| \text{ is even, } i = n$ or $|[n - i] \cap I_1| \text{ is odd}. \text{ Set }$ $I := \{i \in [n] | |[i] \cap I_1| \text{ is even, } i = n \text{ or } |[n - i] \cap I_1| \text{ is odd}\}$, where $[n] := \{1, 2, \ldots, n\}$. Note that $w(U_i) \leq 2$ by Lemma 3.3, and $w(U_i) = 1$ if and only if $i \in I$ for $1 \leq i \leq n$.

**Lemma 5.1.** For $u \in F^n_2$, we have
\[
s_n u = \begin{cases} u, & \text{if } |\Delta(u) \cap I_1| \text{ is even;} \\ u + \sum_{i \in I_0} i, & \text{else.} \end{cases}
\]
In particular,
\[
sw(s_n u) = \begin{cases} sw(u), & \text{if } |\Delta(u) \cap I_1| \text{ is even;} \\ n - |I_1| + 2k - sw(u), & \text{else,} \end{cases}
\]
where $k = |I_1 \cap \Delta(u)|$.

**Proof.** If $|\Delta(u) \cap I_1| \text{ is even then } \langle u, \tilde{S}_i \rangle = 0$ and $s_n u = u$ by construction. If $|\Delta(u) \cap I_1| \text{ is odd},$ then
\[
s_n u = u + \sum_{k=1}^m \tilde{s}_j
= u + \sum_{i \in I_0} i
\]
by Lemma 3.4, and $sw(s_n u) = |\Delta(u) \cap I_1| + (|I_0| - |\Delta(u) \cap I_0|) = n - |I_1| + 2k - sw(u)$. □

The following lemma follows from Corollary 3.8 and $\Delta = \Pi$.

**Lemma 5.2.** The nontrivial orbits of $F^n_2$ under $W_p$ are $U_i$ for $1 \leq i \leq n$. □

The following theorem solves the flipping puzzle when $3 \leq |\Pi_1| \leq n - 3$.

**Theorem 5.3.** Suppose $3 \leq |\Pi_1| \leq n - 3$. Then the nontrivial orbits of $F^n_2$ under $W$ are $U_{A_1}, U_{A_2}, U_{A_3}, U_{A_4}$, where
\[
A_i := \{j \in [n] \mid j \equiv i \mod 4\}.
\]
In particular the number of orbits (including the trivial one) of $F^n_2$ under $W$ is
\[
|\mathcal{O}| = \begin{cases} 3, & \text{if } n \text{ is even;} \\ 4, & \text{else,} \end{cases}
\]
and the maximum-orbit-weight $M(S)$ of $S$ is
\[
M(S) = \begin{cases} 1, & \text{if } A_i \cap I \neq \emptyset \text{ for all } i; \\ 2, & \text{else.} \end{cases}
\]

**Proof.** Fix an integer $1 \leq i \leq n$. By Lemma 5.2, $U_i$ is contained in an orbit of $F^n_2$ under $W$. To put two orbits under $W_p$ to an orbit under $W$ is only by the action of $s_n$. Hence $U_i$ and $U_{n - |I_1| + 2k - i}$ are in the same orbit by Lemma 5.1, where $k$ runs through possible odd integers $|I_1 \cap \Delta(u)|$ for $u \in U_i$. In fact $k$ is an odd number that satisfies $k \leq |\Pi_1|$ and $0 \leq i - k \leq |I_0|$; equivalently
\[
\max\{1, i + |I_1| - n\} \leq k \leq \min\{|I_1|, i\}.
\]
Such an odd integer $k$ exists for any $1 \leq i \leq n$, and note that
\[
n - |Π_1| + 2k - i \equiv n + |Π_1| - i \pmod{4}
\]
since $k$ and $|Π_1|$ are odd integers. To see the orbits as stated in the theorem, it remains to show that $U_i$ and $U_{i+4}$ are in the same orbit under $W$ for $1 \leq i \leq n - 4$. Set $k$ to be the least odd integer greater than or equal to $\max\{1, i + |Π_1| - n + 2\}$. For this $k$, (5.2) holds and then $U_i$ and $U_{n-|Π_1|+2k-i}$ are in the same orbit. Here we use the assumption $|Π_1| \leq n - 3$ to guarantee the existence of such $k$. Note that if we use $(n - |Π_1| + 2k - i, k + 2)$ to replace $(i, k)$ in (5.2), we have
\[
\max\{1, 2k - i\} \leq k + 2 \leq \min\{|Π_1|, n - |Π_1| + 2k - i\}.
\]
The above $k$ and the assumption $3 \leq |Π_1|$ guarantee the Eq. (5.3). Since $n - |Π_1| + 2(k + 2) - (n - |Π_1| + 2k - i) = i + 4$, we have $U_{n-|Π_1|+2k-i}$ and $U_{i+4}$ in the same orbit. Putting these together, $U_i$ and $U_{i+4}$ are in the same orbit. The remaining statements of the theorem are obtained from the orbits description immediately and by using (5.1). □

The following theorem does the remaining cases.

**Theorem 5.4.** Suppose $|Π_1| = 1$, $n - 2$ or $n - 1$. Then the nontrivial orbits of $F_2^n$ under $W$ are
\[
\begin{cases}
U_{n+1-i}, & \text{if } |Π_1| = 1; \\
U_{odd}, U_{2j}, & \text{if } |Π_1| = n - 2; \\
U_{2j-1,2i}, & \text{if } |Π_1| = n - 1
\end{cases}
\]
for $1 \leq i \leq [n/2]$ and $1 \leq j \leq (n - 1)/2$. In particular the number of orbits (including the trivial one) of $F_2^n$ under $W$ is
\[
|\mathcal{P}| = \begin{cases}
(n + 2)/2, & \text{if } |Π_1| = 1; \\
(n + 3)/2, & \text{if } |Π_1| = n - 2; \\
(n + 2)/2, & \text{if } |Π_1| = n - 1,
\end{cases}
\]
and the maximum-orbit-weight $M(S)$ of $S$ is at most 2. Moreover $M(S) = 1$ if and only if
\[
\begin{cases}
\{i, n + 1 - i\} \cap I \neq \emptyset & \text{for all } 1 \leq i \leq [n/2], & \text{if } |Π_1| = 1; \\
\text{odd } i \text{ and } U_{2j} \cap I \neq \emptyset & \text{for all } 1 \leq j \leq [n/2], & \text{if } |Π_1| = n - 2; \\
\{2i - 1, 2i\} \cap I \neq \emptyset & \text{for all } 1 \leq i \leq [n/2], & \text{if } |Π_1| = n - 1.
\end{cases}
\]

**Proof.** As the proof in Theorem 5.3, $U_i$ and $U_{n-|Π_1|+2k-i}$ are in the same orbit under $W$, where $k$ needs to satisfy (5.2). In the case $|Π_1| = 1$, $k = 1$ is the only possible choice and hence $U_{n+1-i}$ is the only orbit under $W_2$ been put together with $U_i$ to become an orbit under $W$. In the case $|Π_1| = n - 2$, we have $k = i - 2$ or $i$ if $i$ is odd; $k = i - 1$ if $i$ is even. In the case $|Π_1| = n - 1$, we have $k = i$ if $i$ is odd; $k = i - 1$ if $i$ is even. In each of the remaining the proof follows similarly. □

**Example 5.5.** Let $S$ be an odd cycle of length $n$, i.e. $n$ is odd, $m = 2$, $j_1 = 1$ and $j_2 = n - 1$. Then $Π_0 = \{1, \bar{n}\}$ and $Π_1 = \{2, 3, \ldots, n - 1\}$. Note that $|Π_1| = n - 2$ is odd, and $I = \{1, 3, \ldots, n\}$. Hence Theorem 5.4 applies. We have
\[
\mathcal{P} = \{U_{odd}, U_0, U_2, U_4, \ldots, U_{n-1}\}.
\]
In particular, $|\mathcal{P}| = (n + 3)/2$, and $M(S) = 2$.

### 6. The case $|Π_1|$ is even

In this section we assume $|Π_1|$ to be even. Recall that in this case $Δ = Π \cup \{\bar{n} + 1\} - \{\bar{n}\}$ and $Δ - \{\bar{n} + 1\}$ are bases of $F_2^n$ and $U$ respectively. Recall that
\[
\bar{1} + \bar{2} + \cdots + \bar{n} = 0.
\]
Let $\overline{U} := F_n - U$, and note that $\overline{U} = \overline{n+1} + U$, $\overline{U}_1 = \{\overline{n+1}\}$ and $U_n = \emptyset$. From Lemma 3.3, for $1 \leq i \leq n - 1$,

$$\tilde{s}_i = \begin{cases} \overline{1} + \overline{2} + \cdots + \overline{i} \in \overline{U}, & \text{if } |[\overline{i}] \cap \Pi_1| \text{ is even;} \\ \overline{1} + \overline{2} + \cdots + \overline{i} + n + 1 \in \overline{U}, & \text{if } |[\overline{i}] \cap \Pi_1| \text{ is odd,} \end{cases}$$

and

$$\tilde{s}_n = n + 1 \in \overline{U}. $$

Moreover, for $1 \leq i \leq n - 1$,

$$sw(\tilde{s}_i) = \begin{cases} i, & \text{if } |[i] \cap \Pi| \text{ is even;} \\ i + 1, & \text{if } |[i] \cap \Pi| \text{ is odd,} \end{cases}$$

and $sw(\tilde{s}_n) = 1$. In other words, there exists a vector in $U$ with simple weight $i$ and weight 1 if and only if $|[i] \cap \Pi| \text{ is even;}$ there exists a vector in $\overline{U}$ with simple weight $i$ and weight 1 if and only if $|[\overline{i}] \cap \Pi_1| \text{ is odd or } i = 1$. Set

$I = \{i \in [n-1] \mid |[i] \cap \Pi_1| \text{ is even}\}$

and

$J = \{i \in [n] \mid |[\overline{i}] \cap \Pi_1| \text{ is odd or } i = 1\}.$

Note that $w(U_i), w(\overline{U}_j) \leq 2,$ and

\[
\begin{align*}
w(U_i) &= 1 \quad \text{if and only if } i \in I; \\
w(\overline{U}_j) &= 1 \quad \text{if and only if } j \in J
\end{align*}
\]

for $1 \leq i \leq n - 1, 1 \leq j \leq n$.

**Lemma 6.1.** For $u \in F_n^\pm$, let $k = |\Pi_1 \cap \Delta(u)|$. Then the following (i), (ii) hold

(i) For $u \in U$, we have

$$s_n u = \begin{cases} u, & \text{if } |\Delta(u) \cap \Pi_1| \text{ is even;} \\ u + \sum_{i \in \Pi_0} i, & \text{else.} \end{cases}$$

In particular, the simple weight $sw(s_n u)$ of $s_n u$ is

$$\begin{cases} sw(u), & \text{if } |\Delta(u) \cap \Pi_1| \text{ is even;} \\ n - |\Pi_1| + 2k - sw(u), & \text{if } |\Delta(u) \cap \Pi_1| \text{ is odd and } \overline{n} \in \Pi_1; \\
sw(u) + |\Pi_1| - 2k, & \text{else.} \end{cases}$$

(ii) For $u \in \overline{U}$, we have

$$s_n u = \begin{cases} u, & \text{if } |\Delta(u) \cap \Pi_1| \text{ is odd;} \\ u + \sum_{i \in \Pi_0} i, & \text{else.} \end{cases}$$

In particular, the simple weight $sw(s_n u)$ of $s_n u$ is

$$\begin{cases} sw(u), & \text{if } |\Delta(u) \cap \Pi_1| \text{ is odd;} \\ n - |\Pi_1| + 2k + 2 - sw(u), & \text{if } |\Delta(u) \cap \Pi_1| \text{ is even and } \overline{n} \in \Pi_1; \\
sw(u) + |\Pi_1| - 2k, & \text{else.} \end{cases}$$

**Proof.** The proof is similar to the proof of Lemma 5.1, except that at this time since the choice of simple basis $\Delta$ is different, the action of $s_n$ on a vector is a little different, and we need to use (6.1) to adjust the simple weight of a vector. $\square$
By Corollary 3.6, the orbits of $F_2^n$ under $W$ (resp. under $W_p$) are divided into two parts, one in $U$ and the other in $\overline{U}$.

**Lemma 6.2.** The nontrivial orbits of $F_2^n$ under $W_p$ are $\overline{U}_i$, $\overline{U}_{i+1,n+1-i}$ and $U_{i,n-i}$ for $1 \leq i \leq \lfloor n/2 \rfloor$. □

**Proof.** By construction, $\overline{U}_i = \{\bar{s}_i\}$ is an orbit under $W_p$. By Corollaries 3.6 and 3.8, $U_i$ is contained in an orbit of $F_2^n$ under $W_p$ and $\overline{U}_i$ is contained in another one for $1 \leq i \leq n - 1$. The Eq. (6.1) and our choice of $\Delta$ imply that $U_i$ and $U_{n-i}$ are in the same orbit of $F_2^n$ under $W_p$; $\overline{U}_{i+1}$ and $\overline{U}_{n+1-i}$ are in another one for $1 \leq i \leq n - 1$. Since no other ways to put these sets together, we have the lemma. □

**Theorem 6.3.** Suppose $4 \leq |\Pi_1| \leq n - 3$. Then the nontrivial orbits of $F_2^n$ under $W$ are $U_{B_1}, U_{B_2}, U_{B_3}, U_{B_4}, \overline{U}_{C_1}, \overline{U}_{C_2}, \overline{U}_{C_3}, \overline{U}_{C_4}$, where

$$B_i = \{j \in [n - 1] | j \equiv i, i + |\Pi_1| - 2, n - i, n - i + |\Pi_1| - 2 \pmod{4}\}$$

and

$$C_i = \{j \in [n] | j \equiv i, i + |\Pi_1|, n + 2 - i, n + 2 - i + |\Pi_1| \pmod{4}\}.$$

In particular, the number of orbits (including the trivial one) of $F_2^n$ under $W$ is

$$|\mathcal{P}| = \begin{cases} 6, & \text{if } n \text{ is even;} \\ 4, & \text{else,} \end{cases}$$

and the maximum-orbit-weight $M(S)$ of $S$ is

$$M(S) = \begin{cases} 1, & \text{if } B_i \cap I \neq \emptyset \text{ and } C_i \cap J \neq \emptyset \text{ for all } i; \\ 2, & \text{else.} \end{cases}$$

**Proof.** Firstly we determine the orbits of $U$ under $W$. By Lemma 6.2, $U_{i,n-i}$ is contained in an orbit under $W$ for $1 \leq i \leq n - 1$. We suppose $\bar{n} \in \Pi_0$ and the case $\bar{n} \in \Pi_1$ is left to the reader. In this case $U_i$ and $U_{i+|\Pi_1|-2k}$ are in the same orbit of $F_2^n$ under $W$ by Lemma 6.1(i), where $1 \leq i + |\Pi_1| - 2k \leq n - 1$ and $k$ runs through possible odd integers $|\Pi_1| \cap \Delta(u)$ for $u \in U_i$. In fact $k$ is any odd number that satisfies $k \leq |\Pi_1| - 1$ and $0 \leq i - k \leq |\Pi_0| - 1$; equivalently

$$\max\{1, i + |\Pi_1| - n + 1\} \leq k \leq \min\{|\Pi_1| - 1, i\}. \quad (6.3)$$

Such an odd $k$ exists for any $1 \leq i \leq n - 3$, and note that

$$i + |\Pi_1| - 2k \equiv i + |\Pi_1| - 2 \pmod{4}. \quad (6.4)$$

To determine the orbits of $U$ in this case, it remains to show that $U_i$ and $U_{i+4}$ are in the same orbit under $W$ for $1 \leq i \leq \lfloor n/2 \rfloor$. Suppose $4 \leq |\Pi_1| \leq 6$. Set $k = 1$ to conclude $U_i$ and $U_{i+2}$ in an orbit if $|\Pi_1| = 4$; $U_i$ and $U_{i+4}$ in an orbit if $|\Pi_1| = 6$. Suppose $|\Pi_1| \geq 8$. Then $n \geq 11$ and $|n/2| \leq n - 6$. Set $k$ to be the least odd integer greater than or equal to $\max\{1, i + |\Pi_1| - n + 3\}$. For this $k$, (6.3) holds and then $U_i$ and $U_{i+|\Pi_1|-2k}$ are in the same orbit. Here we use the assumption $|\Pi_1| \leq n - 3$. Note that if we use $(i + |\Pi_1| - 2k, |\Pi_1| - k - 2)$ to replace $(i, k)$ in (6.3), we have

$$\max\{1, i + 2|\Pi_1| - 2k - n + 1\} \leq |\Pi_1| - k - 2 \leq \min\{|\Pi_0| - 1, i + |\Pi_1| - 2k\}. \quad (6.4)$$

The above $k$, the assumption $4 \leq |\Pi_1|$ and $i \leq n - 6$ guarantee the Eq. (6.4). Since $(i + |\Pi_1| - 2k + |\Pi_1| - 2(|\Pi_1| - k - 2) = i + 4$, we have $U_{i+|\Pi_1|-2k}$ and $U_{i+4}$ in the same orbit. Putting these together, $U_i$ and $U_{i+4}$ are in the same orbit. Then the orbits of $U$ under $W$ are $U_{B_1}, U_{B_2}, U_{B_3}, U_{B_4}$ as in the statement.

Secondly, we determine the orbits of $\overline{U}$ under $W$. Since the proof is similar to the above case, we only give a sketch. By Lemma 6.2, $\overline{U}_{i,n+2-i}$ is contained in an orbit for $2 \leq i \leq n$. We suppose $\bar{n} \in \Pi_1$ and leave the case $\bar{n} \in \Pi_0$ to the reader. By Lemma 6.1(ii), we have $U_i$ and $U_{n-|\Pi_1|+2k+2-i}$ in an orbit, where $k = |\Delta(u)\cap \Pi_1|$ is an even number for some $u \in U_i$ and $1 \leq i \leq n - 4$. From the same argument with $k$ been replaced by $k + 2$, we find $U_{n-|\Pi_1|+2k+2-i}$ and $U_{i+4}$ in an orbit to finish the proof.

The remaining statements of the theorem are obtained from the orbits description. □
The following theorem determine the nontrivial orbits of $F_2^n$ under $W$ in the remaining cases.

**Theorem 6.4.** Suppose $|\Pi_1| = 2$, $n - 2$ or $n - 1$. Then with referring to the notation in Theorem 6.3, the nontrivial orbits of $F_2^n$ under $W$ are

$$
\begin{align*}
U_{i, n-i}, U_{C_1}, U_{C_2}, & \quad \text{if } |\Pi_1| = 2; \\
U_{\text{odd}, U_{2j, n-2j}, U_{\text{odd}, U_{2t, n+2-2t}},} & \quad \text{if } |\Pi_1| = n - 2; \\
U_{2j-1, 2j, n-2j, n-1-j}, U_{2t-1, 2t, n+2-2t, n+3-2t}, & \quad \text{if } |\Pi_1| = n - 1,
\end{align*}
$$

for $1 \leq i \leq \lfloor n/2 \rfloor$, $1 \leq j \leq \lfloor (n - 2)/4 \rfloor$ and $1 \leq t \leq \lfloor n/4 \rfloor$. In particular the number of orbits (including the trivial one) of $F_2^n$ under $W$ is

$$|\mathcal{P}| = \begin{cases} 
(n + 6)/2, & \text{if } |\Pi_1| = 2 \text{ and } n \text{ is even, or } |\Pi_1| = n - 2; \\
(n + 3)/2, & \text{if } |\Pi_1| = 2 \text{ and } n \text{ is odd, or } |\Pi_1| = n - 1,
\end{cases}$$

and the maximum-orbit-weight $M(S)$ of $S$ is at most 2. Moreover $M(S) = 1$ if and only if

$$\{i, n - i\} \cap I \neq \emptyset \quad \text{and} \quad U_{C_j} \cap J \neq \emptyset \quad \text{for } 1 \leq j \leq 2, \quad \text{if } |\Pi_1| = 2;$$

$$\text{odd } \cap I \neq \emptyset, \quad \{2j, n - 2j\} \cap I \neq \emptyset \quad \text{for } 1 \leq j \leq \lfloor (n - 2)/4 \rfloor, \quad \text{if } |\Pi_1| = n - 2;$$

$$\text{odd } \cap J \neq \emptyset, \quad \{2t, n + 2 - 2t\} \cap J \neq \emptyset \quad \text{for } 1 \leq t \leq \lfloor n/4 \rfloor, \quad \text{if } |\Pi_1| = n - 1.$$

**Proof.** The proof is similar to the proof of Theorem 5.4 that follows from the proof of Theorem 5.3. At this time, to determine the orbits of $U$ we check what values of odd $k$ occur in (6.3) in each case of $|\Pi_1| \in \{2, n - 2, n - 1\}$. To determine the orbits of $U$ under $W$, we do similarly as in the second part of the proof of Theorem 6.3. \hfill \square

**Example 6.5.** Let $S$ be an even cycle of length $n$, i.e. $n$ is even, $m = 2, j_1 = 1$ and $j_2 = n - 1$. Then $\Pi_0 = \{I, \Pi\}$ and $\Pi_1 = \{2, 3, \ldots, n - 1\}$. Note that $|\Pi_1| = n - 2$ is even and $I = J = \{1, 2, \ldots, n - 1\}$. Hence Theorem 6.4 applies. We have

$$\mathcal{P} = \{U_{\text{odd}}, U_0, U_{2,n-2}, U_{4,n-4}, \ldots, U_{2j,n-2j}, U_{\text{odd}}, U_{2,n}, U_{4,n-2}, \ldots, U_{2t,n-2t+2}\},$$

where $j = \lfloor (n - 2)/4 \rfloor$ and $t = \lfloor n/4 \rfloor$. In particular

$$|\mathcal{P}| = \lceil (n - 2)/4 \rceil + \lceil n/4 \rceil + 3 = (n + 6)/2,$$

and $M(S) = 2$.

7. Summary

We list the main results as follows. Let $S$ be a connected graph with $n$ vertices $s_1, s_2, \ldots, s_n$ that contains an induced path $s_1, s_2, \ldots, s_{n-1}$ of $n - 1$ vertices, and $s_n$ has neighbors $s_{j_1}, s_{j_2}, \ldots, s_{j_m}$ with $1 \leq j_1 < j_2 \cdots < j_m \leq n - 1$. Let $\overline{s_1}, \overline{s_2}, \ldots, \overline{s_n}$ denote the characteristic vectors of $F_2^n$ and let $s_1, s_2, \ldots, s_n$ denote the flipping moves associated with $s_1, s_2, \ldots, s_n$ respectively. Set

$$\overline{1} = \overline{s_1}, \overline{i + 1} = s_is_{i-1} \cdots s_1 \overline{1} \quad (1 \leq i \leq n - 1), \quad \overline{n + 1} := \overline{s_n}$$

and consider the following three sets

$$\Pi = \{\overline{1}, \overline{s_1}, \ldots, \overline{n}\},$$

$$\Pi_0 = \{i \in \Pi \mid (i, \overline{s_n}) = 0\}.$$

$$\Pi_1 = \Pi - \Pi_0.$$
Thesummary.

| $|I_1|$ is odd | | | |
| $|I_1| = n - 1$, | Odd | $U_{2h-1,2h,n-2h} \cup \overline{U}_{2g+2g+2g, n+3}$ | $2(n + 3)$ |
| $|I_1|$ is even | | | |

where $1 \leq j \leq 4, 1 \leq t \leq \lceil \frac{n}{2} \rceil, 1 \leq i \leq \lfloor \frac{n}{2} \rfloor, 1 \leq h \leq \lfloor \frac{n-2}{4} \rfloor, 1 \leq g \leq \lfloor \frac{n}{4} \rfloor$.

By using the graph structure we can compute the following value

$$|I_1| = \sum_{k=1}^{\lceil \frac{n}{2} \rceil} j_{2k} - j_{2k-1}$$

as shown in Proposition 3.2. Let

$$\Delta := \begin{cases} I_1, & \text{if } |I_1| \text{ is odd;} \\ I_1 \cup \{n + 1 \} - \{n\}, & \text{if } |I_1| \text{ is even} \end{cases}$$

be the simple basis of $F^n_2$ as shown in the beginning of Section 4. For a vector $u \in F^n_2$ let $sw(u)$ denote the simple weight of $u$, i.e. the number nonzero terms in writing $u$ as a linear combination of elements in $\Delta$. Let $U$ be the subspace spanned by the vectors in $I_1$. For $V \subseteq F^n_2$ and $T \subseteq \{0, 1, \ldots, n\}$.

$$V_T := \{u \in V \mid sw(u) \in T\},$$

and for shortness $V_{t_1,t_2,\ldots,t_i} := V_{[t_1,t_2,\ldots,t_i]}$. Let $odd$ be the subset of $\{1, 2, \ldots, n\}$ consisting of odd integers. Set

$$A_i = \{j \in [n] \mid j \equiv i, n + |I_1| - i \pmod{4}\},$$

$$B_i = \{j \in [n-1] \mid j \equiv i, n + |I_1| - 2, n - i, n + |I_1| - 2 \pmod{4}\},$$

$$C_i = \{j \in [n] \mid j \equiv i, i + |I_1|, n + 2 - i, n + 2 - i + |I_1| \pmod{4}\}.$$ 

Let $\mathcal{P}$ denote the set of orbits of the flipping puzzle on $S$. Then the set $\mathcal{P}$ and its cardinality $|\mathcal{P}|$ are given in Table 1 according to the different cases of the pair $(|I_1|, n)$ in the first two columns.

### Appendix

We are indebted to a referee for the information in this section. Let $S$ be a simple connected graph with $n$ vertices and adjacency matrix $A$. The adjacency matrix defines an alternating form $\langle \cdot, \cdot \rangle_A$ on $F^n_2$ by

$$\langle u, v \rangle_A = u^t A v$$

and a quadratic form $q$ on $F^n_2$ that satisfies $q(S) = 1$ and

$$q(u + v) = q(u) + q(v) + \langle u, v \rangle_A$$
for all vertices $s \in S$ and $u, v \in F_2^n$. For a vertex $s \in S$, the associating matrix $s$ in Definition 2.1 satisfies
\[ sA^s = A. \]  \hspace{1cm} (A.1)

Hence $s^t$ is an element of the symplectic group $S(n, F_2)$ [18, p. 69], and therefore the transpose group $W^t$ of the flipping group $W$ of $S$ is a subgroup of $S(n, F_2)$. Moreover $W^t$ preserves $q$ in the sense that $q(w^t u) = q(u)$ for any $w^t \in W^t$ and any $u \in F_2^n$. Note that from Definition 2.1,
\[ s^t u = u + (\bar{s}, u)_A \bar{s} \] \hspace{1cm} (A.2)

for $s \in S$ and $u \in F_2^n$. Such an $s^t$ is called a transvection in the literature. The study of arbitrary groups generated by transvections was largely instituted by McLaughlin [12,13]. Hamelink’s work on Lie algebras led to a question about groups generated by symplectic transvections over $F_2$ [7]. Hamelink’s question was answered by Seidel, as reported and generalized by Shult in his Breukelen lectures [15,17]. Graphical notation is implicit in this earlier work and explicit in that of Brown and Humphries [3,10]. A survey of related work, a brief discussion of Humphries results, and a discussion of the isomorphism types of groups occurring are given by Hall [6]. More recent results are in [14,16].

Let $\mathcal{P}$ denote the set of orbits under the action of $W$ on $F_2^n$. Several of the papers discussed above (or referenced therein) also focus on and discuss orbit lengths for $\mathcal{P}$. As before let $\mathcal{P}$ be the set of orbits under the action of $W$ on $F_2^n$ (the set of orbits of the flipping puzzle on $S$). By (A.1) and using $s^2 = I$, the map
\[ O \rightarrow A O \]
is a map from $\mathcal{P}$ into $\mathcal{P}$, where $AO = \{Au \mid u \in O\}$. In particular if $A$ is nonsingular over $F_2$, this map is a bijection. But when $A$ is singular, the orbit structures can presumably differ. See [9] for more connections between $\mathcal{P}$ and $\mathcal{P}$.
